REDUCTION to the Ecliptic, in Astronomy, is the difference between the argument of latitude, as NP (*Plate XIX. Astronomy, fig. 10.*) and an arc of the ecliptic NR , intercepted between the place of a planet and the node N .

To find the reduction.—The angle of inclination PNR , and the argument of latitude NP , being given, find, by the doctrine of spherics, the arc NR ; subtract NR and NP from each other, the remainder is the reduction.

REDUCTION into first Matter, is a term which alchemists formerly used, when they found their substances putrefy, and grow black.

REDUCTION was more particularly used for the conversion of a dry matter into a liquid, particularly into water; which by the alchemists was held the principle of all things.

The reduction of metals into their first matter, or principles, according to these philosophers, can only be effected by mercury; nothing else being able to loosen the fixed sulphur of metallic bodies, which binds them together.

REDUCTION, in Metallurgy, is the decomposition of a metallic oxyd, so as to leave the metal in a state of greater or less purity, and exhibiting the lustre which is so eminently characteristic of metallic bodies.

Reduction is, for the most part, effected by charcoal and a high temperature, either with or without the assistance of fluxes. For the various modes of reduction in actual practice, see the articles of the different metals.

REDUCTION, in Surgery, denotes an operation by which a dislocated, luxated, or fractured bone is restored to its former place. Reduction, or *reposition*, is always to be performed before any remedy be applied.

REDUIT, in Military Affairs. See **REDUCT.**

REDUNDANCY, or REDUNDANCE, a fault in discourse, consisting in the use of a superfluity of words.

Words perfectly synonymous are redundant, and ought to be retrenched. Redundancy necessarily makes the style weak and languid. See **PLEONASM.**

REDUNDANT HYPERBOLA, in Geometry, is a curve of the higher kind, thus called, because it exceeds the conic section of that name in the number of its hyperbolic legs; being a triple hyperbola, with six hyperbolic legs.

REDUNDANT Interval, in Music, is used for an interval exceeding the truth by a comma.

Some apply redundant to an interval exceeding a diatonic interval by a semitone minor; but this is more usually called a superfluous interval. See **INTERVAL** and **SECOND.**

REDUPLICATION, in Rhetoric, a figure by which a verse begins with the same word as the preceding one ends with. See **ANADIPLOSIS.**

REDUPLICATION, in Logic, is a kind of condition expressed in a proposition, indicating or assigning the manner in which the predicate is attributed to the subject.

The usual reduplicative words are *quatenus, as, so far as, considered as, inasmuch as, &c.* Hence,

REDUPLICATIVE PROPOSITIONS, are such in which the subject is repeated, with some circumstances or condition. Thus, *Men, as men, are rational; kings, as kings, are subject to none but God.*

REDUTEA, in Botany, so called by the late M. Ventenat, in honour of his friend M. P. J. Redouté, one of the most accurate and intelligent botanical draughtsmen, and perhaps the finest botanical painter, ever known. He is the author of a splendid coloured work in folio, on the Liliaceous

liaceous tribe, including some other beautiful plants allied thereto, which has already extended to the seventh volume; and it is to his pencil that the perfection of most botanical works that have appeared in France, for near thirty years past, particularly the publications of L'Heritier and Ventenat, is owing.—Ventenat. *Jard. de Cels*, 11. Poiret in *Lamareck Dict.* v. 4. 87.—Class and order, *Monadelphia Polyanthria*. Nat. Ord. *Columnifera*, Linn. *Malvacea*, Juss.

Gen. Ch. *Cal.* Perianth inferior, double, permanent: the outer of many minute leaflets: inner much larger, of one leaf, in five very deep segments. *Cor.* Petals five, roundish kidney-shaped, imbricated obliquely, united at the base to each other, and to the column of the stamens. *Stam.* Filaments numerous, united below into a conical tube, subdivided and branched above; anthers kidney-shaped. *Pist.* Germen superior, ovate, simple; style thread-shaped, swelling upwards, about as long as the stamens; stigmas three, obtuse. *Peric.* Capsule ovate, of three cells and three valves, the partitions from the middle of each valve. *Receptacles* of the seeds three, inserted into the base of the capsule, alternate with the valves, and nearly equal to them in length, linear, bearing seeds on each edge. *Seeds* six or eight in each cell, obovate, minutely stalked, inserted in two rows on the receptacle, each clothed with dense wool.

Eff. Ch. Calyx double; the outer of many minute leaves; inner in five deep segments. Stigmas three. Capsule of three cells and three valves. Seeds enveloped in wool. Receptacles three, linear, unconnected with the valves.

Obs. Ventenat considers the three distinct receptacles, as affording the most essential distinction, between this and every other malvaceous genus. The woolly seeds, moreover, distinguish it from all except *Gossypium*, whose large three-leaved outer calyx is abundantly different from *Redutea*.

The only known species is

1. *R. heterophylla*. Various-leaved *Redutea*. Vent. *Jard. de Cels*, t. 11.—Discovered by Riedlé in the island of St. Thomas, and raised in M. Cels's garden at Paris. The plant is herbaceous and annual, and M. Ventenat seemed to think it might serve to decorate our flower-borders, like other annuals of very hot climates, in the open air, being, we presume, raised on a hot-bed in the spring. Every part of the herbage is besprinkled with small, whitish, fringed scales, readily seen with a magnifying glass. The root is spindle-shaped, yellowish. *Stem* erect, twelve or fifteen inches high, about the size of a goose-quill, angular, pithy, branched, leafy, dark green, many-flowered. *Leaves* alternate, on longish stalks, spreading widely, ovate, undivided or three-lobed, entire, an inch or inch and half long; paler beneath. *Stipulas* minute, awl-shaped, deciduous. *Flowers* large, handsome, sulphur-coloured, with a dark purple radiating spot at the base of each petal, solitary, erect, on long, simple, axillary stalks. Segments of the inner calyx nearly linear, half as long as the petals. *Style* hairy. *Capsule* the size of a silberd. Wool of the seeds of a dirty grey.—We have not heard of this plant in any English collection.

REDUVIA, in *Surgery*, a word used by some for a whitlow, and by others for a painful crack, or other disorder about the nails, either of the fingers or toes.

REDUX, in *Chemistry*. See REDUCT.

REDWAETH BAY, or *Traeth Coch*, in *Geography*, a bay on the N. coast of the island of Anglesey. N. lat. 53° 17'. W. long. 4° 25'.

REDWITZ, a town of Bavaria, in the bishopric of Bamberg; 4 miles N.N.W. of Künststadt.

REDWITZ, a town of Germany, in the principality of Culmbach; 4 miles N. of Bayreuth.

REDWOOD RIVER, a river of America, which runs into the Wabash, N. lat. 40° 16'. W. long. 87° 5'.

REE, or RE, in *Commerce*. See REES.

REE, *Lough*, in *Geography*, an expansion of the waters of the river Shannon, in Ireland, between the county of Roscommon and the counties of Longford and Westmeath, reaching from Laneshorough nearly to Athlone, with several islands, and in some places three miles broad.

REED, in *Botany*. See ARUNDO.

The root of the *arundo donax* of Dioscorides, attracts any matter lodged in wounds, if powdered and applied to them with wine; or if it is taken fresh and reduced to powder with an onion, or mixed with honey. (*Oribas de Morb. Cur. lib. iii. cap. 32.*) It also removes pains arising from dislocation of limbs, and carries off pains in the hips. The green leaves cut and applied, are said to cure the erysipelas. Poor people boil the flowers in water or in beer, which they mix with honey, and drink, after being filtrated, to cure coughs, oppressions of the breast, and consumptions. The ancients made flutes and other musical instruments of the reed. James's Med. Dict.

REED, *Barr.* See SPARGANIUM.

REED, *Indian flowering*. See CANNA.

REED *Mace*. See TYPHA.

REED, in *Agriculture*, the name of an aquatic plant, infesting boggy lowlands or meadows on the sides of rivers.

The best method of destroying reeds, is by draining the land; for if the drains be cut deeper than their roots it will take away their nourishment, and, consequently, destroy them. Ashes, or soot, will likewise sometimes kill them; and so will ploughing up the land, and laying it in high ridges. They always indicate a deep good moist soil, as a bad one will not nourish or support them. There are many different sorts of reeds, but those of the more strong and tall kinds are often of much use in thatching the different sorts of farm buildings, where other better kinds of coverings are scarce, and these abundant. There is also a sort of reed found in Huntingdonshire, and some of the adjoining counties, that is very valuable for the purpose of laying plaster floors with. In other situations, reeds of the other kinds may be met with, that may be found useful for different purposes either of the farmer or in the arts. In such situations they may be cultivated with advantage as an article of profit: and it may often be more beneficial than to have them destroyed, especially where they are of a valuable nature, and where the land is of too moist and boggy a quality to be ever fully reclaimed and brought into either the state of good arable or meadow ground. Slips on the sides of large rivers or brooks are likewise, frequently, the most advantageously, conveniently, and profitably kept under reed crops, as the overflow of the waters prevent their being usefully managed in any other manner. There are other situations, as those about the borders of large ponds, lakes, and other waters, where they may be preserved with far greater propriety than having them destroyed, provided even that can be accomplished without difficulty, as not any thing more valuable can in general be raised in such places. They are, however, by no means to be continued wherever any better crop will grow and succeed.

REED is also a term applied to such straw of the wheat or rye kinds as has not been bruised by threshing or in any other way.

REED Hedge, in *Gardening*, that sort of hedge fence which is formed from reeds. They are a sort of temporary internal fences made with these dried materials which may be had cheap, and be expeditiously formed into hedges by the assist-

ance of post and railing, being of great utility for occasional use in gardens, to inclose particular internal spaces of ground, so as to afford shelter to certain seedling plants, both in nurseries and large kitchen gardens; and in some nurseries, to form places of shelter for many sorts of seedling trees and shrubs, &c., which being tender whilst young, require the shelter of a fence in winter to break off severe or cutting blasts two or three years, till they gradually gather strength and a greater degree of hardiness. They are also useful in training several sorts of wall-fruit-trees against, to form them for rows, or what are called trained trees; admitting of planting trees against each side of them, six, eight, or ten feet asunder. See NURSERY.

And in large open kitchen-gardens they are occasionally made use of to inclose the melonary, or place for raising early melons and cucumbers in, and often as cross internal fences, under which to form warm borders for the purpose of raising various early crops of esculents.

The proper sort of reeds for these fences are the dried stems of the common marsh reed, which grows in great plenty by river sides, and in lakes, and marshy places, furnishing a crop of stems annually fit to cut in autumn, when they should be bound in bundles, and stacked up, or housed, to remain for use.

These fences are sometimes erected in fixed ranges, and sometimes formed into moveable pannels. In the first mode, some stout posts should be placed six or eight feet asunder, and five or six high, and from post to post carry two or three ranges of flat thin railing, one range near the bottom, another near the top, and a third in the middle; against this railing, the reeds must be placed about two inches thick, having other railing fixed directly opposite; so that the reeds being all along between the double railing, the bottoms resting either upon a plate of wood, or let into the ground, but the former is preferable; and as soon as one pannel is formed, the railing should be nailed as close as possible, driving some long spike-nails through each double railing, or binding them with strong withy bands, or tar rope-yarn, but nailing is the best, in order to bring them as close as may be, to secure the reeds firmly in the proper position; the top should be cut even afterwards.

In the better method, a frame-work of railing should be prepared as above, each pannel six or eight feet long, and the reeds fixed therein as before directed; then, where they are intended to be placed, posts must be ranged six or eight feet distant to support the different pannels. Or sometimes the pannels may be placed inclining against the wall or other fence, in time of severe weather, when the borders are narrow. These sorts of fences are now however in much less use in gardening than formerly.

REED Ronds, in *Rural Economy*, a provincial word, signifying plots or beds of reed, or the swamps in which they grow.

REED, *Ezekiel's*. See *EZEKIEL'S REED*.

REED, *Calamus*, likewise denotes a Jewish measure, otherwise called canna.

REED, in the *Manufactory of Tapestry*. See *TAPESTRY*.

REED Sparrow, in *Ornithology*. See *EMBERIZA Schoeniculus*.

REED Point, in *Geography*, a cape on the W. coast of the island of Antigua. N. lat. 17° 12'. W. long 61° 36'.

REEDHAM. See *REEPHAM*.

REEDS, in a *Fire-ship*, are made up in small bundles of about twelve inches in circumference, cut even at both ends, and tied each with two bands. There are two kinds of them; the long, which are four feet; and the short, which are two feet five inches in length. Some of them are singly

dipped, *i. e.* at one end, the rest are dipped at both ends, in a kettle of melted composition. After being immersed about seven or eight inches in this preparation, and then drained, they are sprinkled over with pulverized sulphur upon a tanned hide. See *FIRE-ship*.

REEDSBOROUGH, in *Geography*. See *READSBOROUGH*.

REEDSTOWN. See *STRONG*.

REEDY CREEK, a river of New Jersey, which runs into the Atlantic, N. lat. 39° 55'. W. long. 74° 16'.

REEDY Island, an island of America, in the Delaware river, 50 miles below Philadelphia, and 20 miles from Bombay Hook, about three miles long and not more than one-fourth of a mile wide. This island was formerly banked in, but is now under cultivation, and overflowed in high tides. It is the rendezvous of outward-bound ships in autumn and spring, waiting for a fair wind. Here is a secure harbour at Port Penn, where piers have been erected by the state of Pennsylvania. On each side of the island is a channel; but vessels, especially of the larger kind, choose to keep the eastern side.

REEDY River. See *SALUDA*.

REEDY River Shoal, a post-town of America, in Greenfield county, South Carolina.

REEF (*reef*, Dutch), in *Navigation*, denotes a certain portion of a sail, comprehended between the top or bottom, and a row of eyelet-holes parallel to it. The intention of the reef is to reduce the surface of the sail in proportion to the increase of the wind; for which purpose there are several reefs parallel to each other in the superior sails, by which they may be still farther diminished, in order to correspond with the several degrees of the gale. The top-sails of ships are usually furnished with four reefs, parallel to the yard; and there are always three or four reefs parallel to the foot of those main-sails and fore-sails which are extended upon booms; a circumstance common to many of the small vessels. Falconer.

A *bag-reef* is the fourth, or lower, reef of a top-sail. A *balance-reef* crosses boom-main-sails diagonally, from the nock to the end of the upper reef-band on the after-larch. This is used to contract the sails in a storm.

REEF also denotes a chain of rocks, lying near the surface of the water.

REEF-Band, in *Sea Language*, a piece of canvas, sewed across the sail, to strengthen it in the place where the eyelet-holes of the reefs are formed.

REEF-Hanks, short pieces of log-line or other small line, fastened at certain distances to form the reefs of boom-sails.

REEF-Tackle, is a rope which passes from the deck to a block at the top-mast head, and thence to another block at the top-sail-yard-arm, where it communicates with another rope, called its *pendant*, that runs downwards through a hole in the yard, and is afterwards attached to a cringle, a little below the lowest reef. It is used to pull the skirts of the reefs close up to the extremities of the top-sail yards, in order to lighten the sail, the weight of which would otherwise render it very difficult to perform this operation. Falconer.

REEF Island, in *Geography*, a small island in the East Indian sea, about 50 miles from the W. coast of Sumatra. S. lat. 4°. E. long. 101° 3'.—Also, a small island in the East Indian sea, near the N. coast of the island of Celebes. N. lat. 0° 8'. E. long. 122° 48'.

REEFING, in *Sea Language*, the operation of reducing a sail, by taking in one or more of the reefs, which is performed by lines, points, or knittles. The top-sails are

always, and the courses generally, reefed with points, which are flat-braided pieces of cordage, whose lengths are nearly double the circumference of the yard. These, being inserted in the eyelet-holes, are fixed in the sail by means of two knots in the middle, one of which is before, and the other behind the reef-band. In order to reef the top-fails with greater facility and expedition, they are lowered down, and made to shiver in the wind, which considerably relaxes their tension. The extremities of the reef are then drawn up to the yard-arms by an assembly of pulleys communicating with the deck, termed the *reef-tackle*; and they are securely fastened to the yard-arms by small cords, called *earings*. The space of sail, comprehended in the reef, is then laid smoothly over the yard, in several folds or doubles; and the whole is completed by tying the points above the yard, so as to bind the reef close up to it. The courses of large ships are reefed either with points or small cords, which are thence called *reef-lines*. In the latter case, the line is passed spirally through the eyelet-holes of the reef, and over the head of the sail alternately, and afterwards strained as tight as possible. It must be observed, however, that the reef-line is sometimes passed round the yard, and sometimes only round the head of the sail; and each of these methods has its advocates. But if it should appear essential to prevent the friction by which a sail is galled between the line and the yard, and as the rope-bands are sufficient to sustain the effort of the sail, it is better to pass the line only round the sail, provided that the turns are inserted through the roband legs; a circumstance carefully practised by every skilful sailer. The same reason may be alleged in favour of tying the points of the courses in the same manner; *i. e.* the after-end of the point should be thrust forward between the head of the sail and the yard; and the fore-end of the said point should come aft over the head of the sail and also under the yard; and thus crossed over the head of the sail, the point should be extended, and the two ends brought over the yard; and tied on the upper side of it as fraight as possible.

When a sail is reefed at the bottom, it is done by knittles, which, being thrust through the eyelet-holes of it, are tied firmly about the space of canvas of which the reef is composed, and knotted on the lower side of the bolt-rope. These knittles are accordingly removed as soon as the reef is let out. Falconer.

REEK, in *Rural Economy*, a term provincially used for stack. See STACK and RICK.

REEK-*Stavel*, a term applied to a frame of wood placed on stone, on which the mow or Itack is raised. It is sometimes written *Reek Staffold*.

REEL, in the *Manufactories*, a machine serving for the office of reeling.

There are various kinds of reels; some very simple, others very complex. Of the former kinds, those most in use are,

1. A little reel, held in the hand, consisting of three pieces of wood, the biggest and longest whereof (which does not exceed a foot and a half in length, and a quarter of an inch in diameter,) is traversed by two other pieces disposed different ways.

2. The common reel, or windlace, which turns upon a pivot, and has four sights, traversed by long pins, or sticks, on which the skain to be reeled is put; and which are drawn closer or opened wider, according to the skain.

Other reels used in particular arts, are explained under their particular articles; as the reel used in milling of silk, under the article MILLING; and that in the reeling or winding of silks, under the article of SILK, &c.

REELS, to reel ropes on from a six-thread ratline to a two-inch rope, have four ribs fixed at each end in a flat circular piece of wood; and round the edges are blades, or handles, to turn them: one of the circular pieces is called the *head*, and is made to slide off for taking the coil away. They turn on an iron spindle, and are from ten to thirty-six inches long, and from twelve to eighteen inches diameter. The *Bench-reel* used by sail-makers is similar to a spinning-wheel, and is used to expedite winding the twine from the skains to the twine-reel. *Log-reels* have several ribs fixed in a circular piece of board at each end, and turn or run upon a spindle, having a handle at one end. (See LOG.) *Twine-reels*, used by sail-makers, are short cylindrical pieces of wood, hollowed in the middle to receive the twine, with a hole through the middle for the spindle. Those used by rope-makers have four oak bars, about eighteen inches long, framed together at the ends on a wooden spindle; one of the bars slides, for the conveniency of taking off the twine. The *Yarn-reel* consists of a circular board fastened horizontally on the middle of a piece of oak four inches square, and sixteen long, with a hole through its middle to receive a bolt, on which it turns as its axis, and is used to wind spun-yarn off the coil. The *Hand-reel* is a narrow board, with three or four holes at each end, in which pegs are fixed for reeling marline and other lines.

REELFOOT, in *Geography*, a small navigable river of America, in Tennessee, which discharges itself into the river Mississippi, about 35 miles S. of the Ohio. It is 30 yards wide seven miles from its mouth. One of its branches rises on the borders of Kentucky.

REELING, in the *Manufactories*, the winding of thread, silk, cotton, or the like, into a skain, or upon a bottom, to prevent its entangling.

It is also used for the charging or discharging of bobbins, or quills, to use them in the manufacture of different stuffs, as thread, silk, cotton, &c.

Reeling is performed different ways, and by different engines.

REEM, in *Zoology*. See RHINOCEROS *Unicornis*.

REEMING, a term used by caulkers for opening the seams of the planks with reeming-irons, that the oakum may be more readily admitted. To make any hole larger is also termed reeming.

REEMING-*Irons*, are the largest irons used by caulkers in opening the seams.

REEMSTOWN, or REAMSTOWN, in *Geography*, a small post-town of America, in Lancaster county, Pennsylvania, situated on a stream which runs into Calico creek, a water of Conestoga, which falls into the Susquehanna; 26 miles N.E. of Lancaster.

REEN, a river of Norway, in the province of Drontheim, which runs into the Glomme; 20 miles N. of Opfal.

REEN *Mossa*, a name used by some for the mountain coralloides, or rein-deer moss.

REENBERG, THEOCARUS, in *Biography*, a celebrated Danish poet, was born at Viborg in 1656, where he was educated. In 1680 he set out on his travels into foreign countries, after having undergone an examination by the theological faculty, and he returned to Denmark in 1682. In 1703 he was appointed fourth judge in Jutland. In 1730 he became counsellor of justice, and he died in 1742. His poetical works were published at Copenhagen in 1769, by his grandson Tielmann, with a preface by Kofod Anker, and annotations by Luxdorph. Gen. Biog.

REENSKLOSSER, in *Geography*, a town of Norway; 12 miles N.N.W. of Drontheim.

RE-ENTERING ANGLE, in *Fortification*. See ANGLE, and CONSTRUCTION, according to M. Vauban's first method.

RE-ENTRY, in *Law*, the refusing or retaking that possession which any one had lately forgone.

As, if I make a lease of land or tenement, I do thereby forego the possession: and if I condition with the lessee, that for non-payment of rent at the day, it shall be lawful for me to re-enter; this is as much as if I conditioned to take again the lands, &c. into my own hands, and to recover the possession by my own act, without the assistance of judge or other process. But words in a deed give no re-entry, if a clause of re-entry be not added. (Wood's Inst. 140.) All persons who would re-enter on their tenants for non-payment of rent, are to make a demand of the rent; and, to prevent the re-entry, tenants are to tender their rent, &c. (1 Inst. 201.) If there is a lease for years, rendering rent, with condition, that if the lessee assigns his term, the lessor may re-enter; and the lessee assigneth, and the lessor receiveth the rent of the assignee, not knowing or hearing of the assignment, he may re-enter, notwithstanding the acceptance of the rent. (3 Rep. 65. Cro. Eliz. 553.) See RENT. A feoffment may be made upon condition, that if the feoffor pay to the feoffee, &c. a certain sum of money at a day to come, then the feoffor to re-enter, &c. Litt. § 322. See ENTRY and USE.

REEPHAM, in *Geography*. See REPHAM.

REER COUNTY. See RIRE.

REERSOE, in *Geography*, a small island of Denmark, in the Great Belt, near the coast of Zealand. N. lat. 55° 32'. E. long. 11° 7'.

REES, REIS, or *Reas*, in *Commerce*, monies of account in Portugal, 1000 of which make a milree or milree. In the notation of accounts, the milrees are separated from the rees by a crossed cypher, called "Cifraon," and the milrees from the millions by a colon; thus Rs. 2 : 700 ⊕ 500, means 2700 mil. and 500 rees. The crusado of exchange, or old crusado, is 400 rees; the new crusado, 480 rees; the testoon, 100; the vintin or vintem, 20 rees. Thus the milree is 2½ old crusados, 2⅓ new ditto, 10 testoons, or 50 vintins. The gold pieces, coined before 1722, are now 20 per cent. higher than their original value; so that the old dobras, coined at 20,000 rees, are worth 24,000; the libonnoies or moidores, coined at 4000 rees, are worth 4800; and the halves and quarters in proportion: but few of these coins are now in circulation. The gold coins, struck since 1722, are the dobra of 12,800 rees; the meia Joanesa, Joanesa, or Portugal piece of 6400 rees; the half Joanesa, of 3200; the dezefeis testoons, of 1600; the quatingo, of 1200; the oito testoons, of 800; the old crusado, of 400, now very scarce; and the new crusado, of 480 rees. The silver coins are new crusados, of 480 rees; halves, quarters, and eighths, or pieces of 240, 120, and 60 rees; testoons of 100, and halves of 50; and vintins of 20 rees. There are also copper pieces of 10, 5, 3, and 1½ rees. The pieces coined in Brazil, called patacas, of 600 and 640 rees, are current only in that country, and their intrinsic value is 10 per cent. less than that of the Portugal coins. There is, besides, a gold milree, struck for the Portuguese possessions in Africa, and also a silver coin, of the value of 12 macntas, or 600 rees; the macnta being a money of account, worth 50 rees. The Spanish patacas, or dollar, are reckoned at Lisbon at 830 rees, more or less.

Portuguese gold coins are 22 carats (the mark fine being 24 carats), wrought gold is 20½ carats, and gold dust from 21¾ to 22 carats fine. The fineness of silver is expressed in dinheiros and grains, the mark fine being 12 dinheiros, and the dinheiro subdivided into 24 grains. Silver coins are

10 dinheiros 19 grains fine, and wrought silver 10¼ fine. The rate of coinage of gold and silver coins is as follows: 8 dobras of 12,800 rees, 16 Joaneses of 6400 rees, 32 half Joaneses of 3200 rees, 64 dezefeis testoons, 128 oito testoons, or 256 old crusados, are to weigh a Portuguese mark of gold, 22 carats fine. Hence (the mark being 3542½ English grains) the dobra contains 442½ grains; the piece of 6400 rees 221½ grains of English standard gold, and the other pieces in proportion. These coins, moreover, are not, in general, exactly 22 carats fine; but there is a remedy which amounts from ⅓ to ⅔ of a carat; and the new crusados are found to be only 21⅓ carats fine. The silver coin is 10 din. 19 gr. as above; and the mark is coined into 13½ new crusados; hence the new crusado weighs 345½ Portuguese grains, or 265½ English grains; halves, quarters, and eighths, in proportion. It, therefore, contains 258½ grains of English standard silver. The gold piece of 6400 rees is worth 35s. 11d. sterling; and the old crusado, 2s. 3d.; and thus the milree, valued in gold, is worth 67¼d. sterling. The new silver crusado is worth about 2s. 9d. sterling; and, therefore, the milree, valued in silver, is worth 68¾d. sterling. Gold is to silver as 16 to 1.

At Bombay each quarter of a rupce is divided into 100 rees. See RUPEE.

REES, in *Geography*, a town of the duchy of Cleves; 8 miles E. of Cleves. N. lat. 51° 47'. E. long. 6° 20'.

REES ul Ain, or *Resaina*, a town of Asiatic Turkey, in the province of Diarbekir; 80 miles S. of Diarbekir.

REETZ, a town of the New Mark of Brandenburg; 50 miles N.E. of Custrin. N. lat. 53° 18'. E. long. 15° 56'.

REEVE, in *Ornithology*, the name of a bird which is the female of the *avis pugnax*; the male of which, from the long feathers round his neck, is called the *ruff*. See TRINGA Pugnax.

REEVE of a Church, is the guardian of it, or the churchwarden.

So *shire-reef* is the sheriff, or guardian of a county; and *port-reeve*, the warden of a port or haven.

REEVE-LAND. See REVELAND.

REEVING, in the *Sea Language*, is the putting a rope through any hole, as the channel of a block, &c. Hence, to pull a rope out of a block, is called *unreeving*.

RE-EXCHANGE, in *Commerce*, a second payment of the price of exchange, or rather the price of a new exchange, due upon a bill of exchange that comes to be protested; and to be refunded the bearer, by the drawer or indorser. See EXCHANGE.

The occasion of re-exchange is, when the bearer of a bill of exchange, after protesting it, for want either of acceptance, or of payment, borrows money on his own promise, bond, or the like; or draws a bill of exchange in the place where the payment was to be made, on the person who furnished the first for which he pays a second exchange; which, being added to the first already paid, the drawer of the first bill is answerable for two exchanges, properly called *exchange* and *re-exchange*.

The bearer of a protested bill has a right to recover both the one and the other on the drawer. Yet the simple protestation which the bearer makes in the act of protest, that he will take up a like sum at re-exchange, for want of his bill being accepted or paid, is not sufficient to entitle him to demand the reimbursement of his re-exchange, unless he make it appear, that he has actually taken up money in the place on which the bill was drawn.

Otherwise the re-exchange will only amount to the restitution of the first exchange, with interest, the expences of protesting, and those of the journey, if there have been any.

If a bill of exchange, payable to the bearer or order, come to be protested, the re-exchange is only due upon the drawer for the place where the remittance was made, not for those places where it may have been negotiated; at least the drawer has a right to be refunded his re-exchange for those places by the indorser.

Indeed, the re-exchange is due from the drawer upon all places where a power of negotiation is given by the bill; and upon all others, if the power of negotiating be indefinite.

Lastly, the interest of the re-exchange, of the expences of the protest, and the journey, are only due from the day of the demand.

It is supposed to be the Gibelins driven out of Italy by the faction of the Guelfs, and sheltered at Amsterdam, who first established the custom of re-exchange, on pretence of the interests, damages, and expences they underwent, when the bills given them for the effects they had been obliged to abandon, were not accepted, but came to be protested.

RE-EXTENT, in *Law*, a second extent made upon lands or tenements, on complaint that the former extent was partially made. See EXTENT.

REFAH, in *Geography*, a town of Egypt, on the coast of the Mediterranean, anciently called "Raphia," (which see); 18 miles N.E. of El Arish.

REFECTION, REFECTIO, among *Monks* and *Ecclesiastics*, a spare meal or repast, just sufficing for the support of life.

REFECTION is also used, in *Ancient Authors*, for a duty or service incumbent on any person to provide meals for ecclesiastics, or even for princes.

REFECTORY, or REFECTUARY, *Refectorium*, a spacious hall in convents, and other communities, where the monks, nuns, &c. take their refectious or meals in common.

The refectory of the Benedictines of St. George at Venice, designed by Palladio, is one of the finest in the world. Daviler.

REFERENCE, in *Writing*, &c. a mark relative to another similar one in the margin, or at the bottom of the page, where something, omitted in the text, is added; and which is to be inserted either in reading or copying. A copyist must be very expert at taking references.

References are also used in books, where things being but imperfectly handled, the reader is directed to some other part or place where they are more amply explained.

Dictionarys are full of references, denoted by *see* or *vide*.

By means of these references the dictionary writer settles a correspondence between the several parts of his work, and may give his dictionary most of the advantages of a continued treatise.

Indices or tables are only references to the several parts of the work where the several matters are handled.

REFERENCE, in *Law*, denotes the sending of any matter by the court of chancery to a master; and by the courts at law to a prothonotary, or secondary, to examine and report to the court. (2 Lil. Abr. 432.) If a matter in difference be referred to the secondary, and one of the parties will not attend at the time appointed, after notice given, to hear the business referred; the other party may proceed in the reference alone, and get the secondary to make his report without hearing of the party not attending. (2 Lill. 342.) If a question of mere law arises in the course of a cause in chancery, as whether, by the words of a will, an estate for life or in tail is created, or whether a future interest devised by a testator shall operate as a remainder on an executory devise; it is the practice of that court to refer it to the opinion of the judges of the court of king's bench, or common

pleas, upon a case stated for that purpose, in which all the material facts are admitted, and the point of law is submitted to their decision; who thereupon have it solemnly argued by counsel on both sides, and certify their opinion to the chancellor: and on such a certificate the decree is usually founded. It seems that the master of the rolls, sitting for the chancellor, may make such reference; but not when sitting at the rolls. 2 Bro. C. C. 88.

The court of exchequer is both a court of law and of equity: therefore, if a question of mere law arises in the course of the exercise of its equitable jurisdiction, the barons will decide upon it in that suit, without referring it to another jurisdiction. Bl. Comm. iii.

REFERENDARY, REFERENDARIUS, in *Ancient Customs*, an officer who exhibited the petitions of the people to the king, and acquainted the judges with his commands.

An officer of this kind, Spelman observes, we had in England, in the time of the Saxons. The like office was afterwards discharged by others, called masters of requests.

REFINING, in *Metallurgy* and *Affaying*. In the former it signifies the means of obtaining metals from their ores, and from any other impurities, natural or artificial: for which see the metals under their respective heads. In the latter it is employed for ascertaining the quantity of the noble metals in the different alloys: for which see CUPEL; where the methods of refining in the furnace are fully treated. And for the humid process called *parting*, see GOLD.

It may be proper here to observe, that although the process of parting by nitric acid is still practised, we are inclined to recommend the method proposed by Bergmann, which consists in dissolving the alloy of gold and silver in nitro-muriatic acid. The silver falls to the bottom in the state of muriate of silver, and the gold is precipitated by the green sulphate of iron. The gold, by this means, is obtained perfectly pure, which is seldom the case in the process of parting. The trouble of testing to know what silver to add to the alloy, to make the gold equal to one-fourth of the silver, will be saved, and, with heat, the nitro-muriatic acid dissolves the gold quite as soon as the silver is dissolved in the common method. The muriate of silver, which is easily separated by washing, may be readily reduced by heating it with soda in an iron crucible. The soda combines with the muriatic acid, and is sublimed in white fumes.

REFINING of *Sugar*. This operation is begun by several strong lixiviums or leys of lime-water and eggs, shells and all, mixed and beaten together.

The first refining is performed in the Caribbees, and other places, where the sugar-canes are cultivated; and only serves to make the brown or coarse sugars.

When these are imported into Europe, the sugar-bakers take them up, and refine them farther, by a second operation, or rather a repetition of the first.

To render the sugar very fine, fit for confections, &c. they give it a third refining; in which they only use the whites of eggs and their shells beaten together, and thrown into the melted sugar; which is called *clarifying the sugar*. See SUGAR.

REFINING of *Salt-petre*. The salt being put into an earthen or iron vessel, as much spring-water is poured on it as suffices to dissolve it. The vessel is then put over a gentle fire; and as soon as the water begins to boil, alum powder is thrown into it: the proportion is, one pound of alum to one hundred and twenty-eight pounds of salt-petre; and a little vinegar is added. As it boils, the scum is to be taken off; and it is to be evaporated till a pellicle appears on it, and then set to shoot.

For the refining of other matters, as camphor, cinnabar, sulphur, salt, borax, &c. see CAMPHOR, CINNABAR, SULPHUR, SALT, &c.

REFIRTH VOE, in *Geography*, a bay on the E. coast of the island of Yell. N. lat. $60^{\circ} 58'$. W. long. $1^{\circ} 25'$.

REFITTING, in *Sea Language*, denotes the repairing of any damages which a ship may have sustained in her sails and rigging, by battle or tempestuous weather.

REFLECTED RAY. See RAY.

REFLECTED *Vision*. See REFLEX and VISION.

REFLECTING, or REFLECTIVE *Dial*, is a sort of dial, which shews the hour by means of a thin piece of looking-glass plate, duly placed to cast the sun's rays to the top of a ceiling, on which the hour-lines are drawn.

REFLECTING *Microscope*. See MICROSCOPE.

REFLECTING *Level*. See LEVEL.

REFLECTING *Telescope*. See TELESCOPE.

REFLECTION, or REFLEXION, in *Mechanics*, the return, or regressive motion of a moveable, occasioned by the resistance of a body, which hindered its pursuing its former direction.

It is controverted whether there be any moment's rest or interval between the incidence and the reflection. For the affirmative stand the Peripatetics, and all who conceive the reflected motion to be different from the incident one of the same body. The motion of incidence, according to these authors, is wholly lost, and destroyed, by the resistance of the obstacle struck against; and the moveable is thus rendered absolutely quiescent in the point of contact, till a new motion of reflection is produced in it, from a contrary cause.

The Cartesians assert the negative; absolutely denying any rest at all between the incidence and reflection: urging, that if the motion were once destroyed, though but for a moment, there would be nothing to excite it again; but the body would persevere in that new state, as much as if it had been at rest a thousand years.

Accordingly Rohault, and others, define reflection to be no other than a change of determination; or a continuation of the former motion in a new direction.

As, say they, a pendulum, when arrived at its greatest sweep, does not stop; so a hard body, by striking on another hard one, does not rest, but pursues its motion the contrary way, according to the established law of nature; and this from the immediate influence or impulse of the cause that first moved it. But this doctrine is now generally set aside.

Reflection is conceived, by the latest and best authors, as a motion peculiar to elastic bodies, whereby, after striking on others which they cannot remove, they recede, or turn back by their elastic power.

On this principle, it is asserted, that there may be, and is, a period of rest between the incidence and the reflection; since the reflected motion is not a continuation of the other, but a new motion, arising from a new cause or principle, viz. the power of elasticity.

It is one of the great laws of reflection, that the angle a reflected body makes with the plane of a reflecting obstacle, is equal to that in which it struck on that obstacle. For the several laws of motion observed in the reflections of bodies, see PERCUSSION.

REFLECTION of the rays of light, in *Optics*, is a motion of the rays, by which, after impinging on the solid parts of bodies, or rather, after a very near approach to them, they recede, or are driven from them.

When rays of light arrive at a surface, which is the boundary of two mediums not homogeneous, they continue

their progress without deviating from those planes in which their former paths lay, and which are perpendicular to the surface of the mediums, but they no longer retain the same direction, a part of them, and sometimes nearly the whole, being reflected back from the surface, while the remaining part is transmitted and refracted, or bent. No instance occurs of the abrupt change of the density of a medium, without a partial reflection of the light passing either into the denser, or into the rarer medium; and the more obliquely the light falls on the surface, the greater, in general, is the reflected portion. No body is so black as to reflect no light at all, and to be perfectly invisible in a strong light; although at the surface separating two very rare bodies, as two kinds of gas, the reflection is too faint to be perceptible; but in this case the separation is seldom perfectly abrupt. The quantity of light reflected, when other circumstances are equal, appears to be always greatest when the difference of the optical or refractive density of the two substances is the greatest. Thus, the reflection from the common surface of glass and water is much weaker than from a surface of glass exposed to the air. Metals, in general, reflect a great proportion of the light falling on them; and even the reflection from the common surface of glass and mercury appears to be but little weaker than the reflection from the surface of mercury immediately exposed to the air, so that the optical density of the metals must be exceedingly great. It appears, also, that a portion of the light falling on a reflecting surface, is always transmitted to a certain depth, notwithstanding the apparent opacity of any large masses of the substance. Thus, if we cover a small hole of a window-shutter with the thinnest leaf-gold, we shall find that it transmits a greenish light, which must have passed the reflecting surface, but which, if the gold had been but one ten-thousandth of an inch in thickness, would have been wholly interrupted, and probably in the same manner as by passing through 700 feet of water. See LIGHT and REFRACTION.

The reflection of the rays of light from the surfaces of bodies, is the means by which bodies become visible.

And the disposition of bodies to reflect this or that kind of rays most copiously, is the cause of their being of this or that colour.

The reflection of light from the surfaces of mirrors, makes the subject of *catoptrics*; which see. See also MIRROR.

The reflection of light, sir Isaac Newton has shewn, is not effected by the rays striking on the very parts of the bodies; but by some power of the body equally diffused throughout its whole surface, by which it acts upon the ray, attracting or impelling it without any immediate contact.

This power he shews to be the same, by which, in other circumstances, the rays are refracted; and by which they are at first emitted from the lucid body. See REFRACTION.

The arguments he produces to prove this are as follow: 1. Because the surfaces of polished glasses, which to the eye appear smooth, are yet, in reality, very rugged and uneven (polishing being nothing but the grating, scratching, and breaking off the coarser protuberances, by means of sand, glass, putty, tripoli). If the rays of light, therefore, were reflected by striking on the solid parts of the glass, the reflections would never be so accurate as we find they are, but the rays would even be as much scattered by the most polished glass, as by the roughest. It remains, therefore, a problem how glass, polished by fretting substances, can reflect light so regularly as it does; which problem is scarcely otherwise to be solved, than by saying, that the reflection of a ray is effected, not by a single point of the reflecting

REFLECTION.

reflecting body, but by some power of the whole body, evenly diffused all over its surface, and by which it acts on a ray without immediate contact; for that the parts of bodies do act upon light at a distance, is already shewn under the articles INFLECTION and LIGHT.

2. If the colours, separated by a prism placed at the entrance of a beam of light into a darkened room, be successively cast on a second prism placed at a greater distance from the former, in such manner as that they all fall alike, or with an equal obliquity, upon it; the second prism may be so inclined to the incident rays, that those which are of a blue colour shall be all reflected by it; and yet those of a red colour pretty copiously transmitted. Now, if the reflection were caused by the parts of the air or glass, we would ask, why, at the same obliquity of incidence, the blue should wholly impinge on those parts so as to be all reflected; and yet, the red find pores enough to be, in a great measure, transmitted.

3. Where two glasses touch one another, there is no sensible reflection; and yet we see no reason why the rays should not impinge on the parts of the glass, as much when contiguous to other glass, as when contiguous to air.

4. When the top of a water bubble, by the continual subsiding and exhaling of the water, grows very thin, there is such a little, and almost insensible quantity of light reflected from it, that it appears intensely black; whereas round about that black spot, where the water is thicker, the reflection is so strong, as to make the water seem very white. Nor is it only at the least thickness of thin plates or bubbles, that there is no manifest reflection, but at many other thicknesses, gradually greater and greater. For, in one of our author's observations, the rays of the same colour were, by turns, transmitted at one thickness, and reflected at another thickness, for an intermediate number of successions: and yet, in the superficies of the thinned body, where it is of one thickness, there are as many other parts for rays to impinge on, as where it is of any other thickness.

5. If the red and blue rays, separated by a prism, fall successively on a thin plate of any pellucid matter, whose thickness increases in continual proportion, (such as a plate of air between two glasses, the one plane, and the other a little convex,) the same plate will, in the same part, reflect all the rays of one colour, and transmit all those of the other; but, in different parts, will reflect the rays of one and the same colour at one thickness, and transmit them at another; and thus alternately, and *in infinitum*. Now, it can never be imagined that at one place the rays, which, for instance, exhibit a blue colour, should happen to strike on the solid parts, and those which exhibit a red, to hit on the void parts of the body; and at another place, where the body is either a little thicker, or a little thinner, that, on the contrary, the blue should hit on the pores, and the red upon the solid parts.

6. In the passage of light out of glass into air, there is a reflection as strong as in its passage out of air into glass, or rather a little stronger, and by many degrees stronger than in its passage out of glass into water. Now, it seems improbable, that air should have more reflecting parts than water or glass: but if that should be supposed, yet it will avail nothing; for the reflection is as strong, or stronger, when the air is drawn from the glass by the air-pump, as when it is adjacent to it. If any should here object, on Descartes's hypothesis, that, though the air be drawn away, there is a subtle matter remaining to supply its place, which, being of a denser kind, is better fitted for the reflection of light than any other body; besides that we have elsewhere shewn such subtle matter to be fictitious, and that, suppos-

ing its existence, and its reflecting power, no light could ever have been propagated, but must have been all reflected back to the lucid body, immediately after it was first emitted, the following experiment does evidently convict it of falsity.

7. If light, in its passage out of glass into air, strike more obliquely than at an angle of forty or forty-one degrees, it is then wholly reflected: if less obliquely, it is in great measure transmitted. Now, it is not to be imagined, that light at one degree of obliquity should meet with pores enough in the air to transmit the greater part of it, and at another degree should meet with nothing but parts to reflect it wholly; especially considering, that, in its passage out of air into glass, how oblique soever be its incidence, it finds pores enough in the glass to transmit a great part of it. If any suppose, that it is not reflected by the air, but by the utmost superficial parts of the glass, there is still the same difficulty: besides, that such a supposition is unintelligible, and will also appear to be false, by applying water behind some part of the glass, instead of air; for so in a convenient obliquity of the rays, suppose of forty-five or forty-six degrees, at which they are all reflected, where the air is adjacent to the glass, they shall be in great measure transmitted where the water is adjacent to it; which argues, that their reflection or transmission depends on the constitution of the air and water behind the glass, and not on the striking of the rays upon the parts of the glass, the rays not being reflected until they have reached the last part of the surface, and have begun to go out. For if, in going out, they fall upon a surface of oil and water, they proceed, the attraction of the glass being balanced by an equal force the contrary way, and prevented from having its effect by the attraction of the liquor adhering to it: but if the rays, in passing out of this last surface, fall into a vacuum, which has no attraction, or into air, which has but little, not enough to counterbalance the effect of the glass in this case, the attraction of the glass draws them back, and reflects them.

This will appear still more evident by laying two glass prisms, or the object-glasses of two telescopes, the one plane, and the other a little convex, upon each other, so as they may neither touch, nor yet be too far apart; for that light which falls on the hinder surface of the first glass, where the glasses are not above $\frac{1}{10}$ th part of an inch apart, will be transmitted through the surface, and through the air or vacuum between the glasses, and will pass into the second glass; but if the second glass be taken away, then the light passing out of the second surface of the first glass into the air or vacuum, will not proceed, but will return into the first glass, and be reflected.

Whence it follows, that the rays are drawn back again by some force in the first glass, there being nothing else to occasion their return. And hence too it follows, that the reflection is not effected by means of any subtle matter contiguous to the hinder surface, according to the principles of Descartes; since that matter ought to reflect them when the glasses were nearly contiguous, as well as when the second glass is quite removed.

Lastly, if it be asked, how some of the rays come to be reflected, and others transmitted; and why they are not all alike reflected, supposing the reflection owing to the action of the whole surface? the same great author shews, that there are, both in the rays of light, and in the bodies themselves, certain vibrations (or some such property) impressed on the rays, by the action either of the luminary that emits them, or of the bodies that reflect them; by means of which it happens that those rays, in that part of their vibration

REFLECTION.

which conspires with the motion of the parts of the body, enter the body, are refracted and transmitted; but those in a contrary part of their vibration are reflected.

Add, that every ray of light, in its passage through any refracting surface, is put into a certain transient constitution or state, which, in the progress of the ray, returns at equal intervals, and disposes the ray, at each return, to be easily transmitted through the next refracting surface; and between each return, to be easily reflected by it.

These alternate dispositions, which sir Isaac Newton calls *fits of easy reflection*, and of *easy transmission*, he accounts for by supposing, that they are occasioned by the vibrations of a subtle fluid, in which the ray passes, which happening to move faster than the rays, when a ray is in that part of the vibration which conspires with its motion, it passes through; but when in the contrary part of the vibration, it is beat back again: whence every ray is successively disposed to be easily reflected, or easily transmitted, by every vibration which overtakes it.

He also thought that these vibrations might be excited by the mutual action and re-action of light, of bodies and of this medium, at the instant of reflection or refraction; so that, in fact, he supposes two causes of this disposition to be reflected or transmitted, when rays of light arrive at any new surface. One of them is the regular vibration of the ethereal medium, affecting them through the whole of their progress from the luminous body; and the other the tremulous motion, or irregular vibration of the same medium at the surfaces of bodies, occasioned by the action and re-action between light and them: for this last cause can hardly be supposed to affect the whole ethereal medium equally, and produce the regular returns of these fits in every ray.

M. Boscovich supposes with Newton, that the fits of reflection or transmission affect the rays themselves, in the whole of their passage from the luminous body, but that they arise from an alteration in their form, by means of the elasticity of their component parts, having been originally driven from the luminous body by a force which acted more strongly on the hinder parts than on the rest of the mass, and thereby put them into a vibratory motion. He also supposes, that the intervals of the fits of easy reflection and transmission may be different in different rays, on the three following accounts. 1. The rays that are differently refrangible have different velocities, at least after refraction; so that, though the fits should return at equal intervals, it will affect different rays in different parts of their progress. 2. The unequal action between the points that compose the same particle of light may make a difference in their oscillations, at the time of changing their medium. And lastly, rays coming in different inclinations to the new surface, the internal motions of these points will be in different directions with respect to the surface, and consequently the whole mass of the medium will act upon all the points differently. Boscov. *Theoria*, p. 232.

Upon the whole, says Dr. Priestley, is it not more probable that the rays of light are transmitted from the sun, with an uniform disposition to be reflected or refracted, according to the circumstances of the bodies on which they impinge; and that the transmission of some of the rays under the same circumstances, apparently, with others that are reflected, is owing to the minute vibrations of the small parts of the surfaces of the mediums through which the rays pass; vibrations that are independent of action and re-action between the bodies and the particles of light at the time of their impinging, though probably excited by the action of preceding rays. As to the transmission or reflection of certain kinds of light only, producing colours in thin plates,

the cause may be this; *viz.* that every particle of the medium has a great number of equal alternate intervals of attraction and repulsion, relatively to the particles of light; but that these intervals are of different magnitudes, according as the particles of light are of different colours. Now if the thickness of any transparent medium in which the particles of matter are uniformly placed is such, that the attracting intervals of the extreme particles, as well as the repelling intervals, coincide with one another, *i. e.* attracting with attracting, and repelling with repelling, in regard to any one kind of rays, *e. g.* the red; by the united force of these extremes, (all the intermediate particles of the medium mutually destroying each other's effects,) these rays will be reflected. But where the plate is of an intermediate thickness between this and the next thickness, where the attracting intervals coincide, attracting with attracting, and repelling with repelling, the attracting intervals will coincide with the repelling ones, and the repelling ones with the attracting ones, and these mutually destroying one another's effects, these rays will pass on freely, and be transmitted. But as the intervals of attraction and repulsion are different for differently coloured rays, the thickness of the plates at which these coincidences will or will not happen, in the differently coloured rays, will be different. So that it appears probable, says Dr. Priestley, in conformity to a doctrine first suggested to him by Mr. Michell, that the whole mystery of coloured plates depends upon the attractions and repulsions of the particles of the bodies that compose them, affecting different rays in a different manner, according to their thickness. *Hist. &c. of Light and Colours*, p. 309, &c. See *COLOURS of thin Laminæ, &c.* and *RINGS of Colours*.

Sir Isaac Newton concludes his account of the reflection of light with observing, that if light be reflected not by impinging on the solid parts of bodies, but by some other principle, it is probable that as many of its rays as impinge on the solid parts of bodies are not reflected, but stifled and lost in the bodies. Otherwise, he says, we must suppose two kinds of reflection; for should all the rays be reflected which impinge on the internal parts of clear water or crystal, those substances would rather have a cloudy colour than a clear transparency. To make bodies look black, it is necessary that many rays be stopped, retained, and lost in them; and it does not seem probable, that any rays can be stopped and stifled in them, which do not impinge on their parts: and hence, he says, we may understand, that bodies are much more rare and porous than is commonly believed. However, M. Bouguer disputes the fact of light being stifled or lost by impinging on the solid parts of bodies. See *ABSORBING*.

For other facts and observations relating to the subject of this article, see *LIGHT*. See also *RAYs of Light*, and *RAYs of Heat*.

REFLECTION, in *Catoptrics*, is the return of a ray of light from the polished surface of a speculum or mirror, as driven thence by some power residing in it.

The ray, thus returned, is called a *reflex*, or *reflected ray*, or a *ray of reflection*; and the point of the speculum, whence the return commences, is called the *point of reflection*.

Thus the ray AB (*Plate I. Optics, fig. 3.*) proceeding from the radiant A, and striking on the point of the speculum B, being returned thence to C, BC represents the *reflected ray*, and B the *point of reflection*; in respect of which AB represents the *incident ray*, or *ray of incidence*, and B the *point of incidence*.

Again, a line CG drawn from any point, as C, of the reflected

REFLECTION.

reflected ray BC, perpendicular to the speculum, is called the *cathetus of reflection*, or *cathetus of the eye*: as a line AF, drawn from the radiant perpendicular to the speculum, is called the *incidence*.

Of the two angles which the reflected ray BC makes with the mirror, the smallest, CBE, is called the *angle of reflection*: as of the two angles the incident ray makes with the speculum, the smallest, ABD, is called the *angle of incidence*.

If the mirror be either concave or convex, the smallest angles the ray makes with the tangent to the point of reflection and incidence, are the angles of reflection and incidence.

The angle CBH, which the reflected ray makes with a perpendicular to the point of reflection, is called the *inclination of the reflected ray*: as the angle ABH is called the *inclination of the incident ray*.

REFLECTION, *general laws of*.—I. *If a ray of light be reflected from a speculum of any form, the angle of incidence is ever equal to the angle of reflection*. This law obtains in percussions of all kinds of bodies; and consequently must do so in those of light. See *Laws of PERCUSSION*; see also *ANGLE*.

It might therefore be here assumed as an axiom: but it is of that importance, and its demonstration so beautiful, that we cannot omit it. Suppose, then, DC (*Plate XVII. Optics, fig. 14.*) an incident ray, propagated from the radiant D: here, though the motion of the ray be simple, yet its determination in the line DC, being oblique with respect to the obstacle, is really compounded of two determinations; the one along DE, the other along DG.

The force along DC, therefore, is equal to the two forces along DG and DH. But the obstacle GF only opposes one of the determinations: *viz.* that along DG (for it cannot oppose a determination parallel to itself, as DE): therefore, only the force along DG will be lost by the stroke, that along DH or GC remaining entire. But a body perfectly elastic (such as we suppose the ray of light) will recover by its elasticity the force it lost by the shock.

The ray, therefore, will recover the force DG or CH: thus, retaining both its forces, and both its former determinations HC and CF, after percussion, it will be impelled along CF and CH by the same forces as before along DH and DG. By its compound motion, therefore, it will describe the right line CE, and that in the same time as DC; and HE and DH will be equal, as being described by the same force. Now, the two triangles DCH and CHE are equal, and consequently their similar angles are equal. Since then HCA = HCF; DCA, the angle of incidence, is equal to ECF, the angle of reflection. Q. E. D.

This law is confirmed in light by an easy experiment. For a ray of the sun falling on a mirror, in a dark room, through a little hole, you will have the pleasure to see it rebound, so as to make the angle of reflection equal to that of incidence. See *CAMERA Obscura*.

The same may be shewn various other ways: thus, *e. gr.* placing a semicircle FiG, (*Plate I. Optics, fig. 3.*) on a mirror DE, its centre on B, and its limb perpendicular to the speculum; and assuming equal arcs, Fa and Ge, place an object in A, and the eye in C: then will the object be seen by a ray reflected from the point B. And if B be covered, the object will cease to be seen.

For the conclusions drawn from this general doctrine of reflection, see the *doctrine of MIRRORS, &c.*

II. *Each point of a speculum reflects rays falling on it,*

from each part of an object. See the doctrine of MIRRORS, &c.

III. *If the eye C, and the radiant point A, change places, the point will continue to radiate upon the eye, in the same course or path as before.*

For if the object be removed from A to C, it will still radiate on its former point of reflection, B; but there can be but one right line drawn between the two points G and D; and the rays are right lines. Therefore, that which was before the ray of reflection, will now be the ray of incidence; and since it will be reflected under the same angle as that under which it fell, that which was before the ray of incidence, will now be the ray of reflection. So that the object removed to C, will radiate on the eye placed in A, by the right lines CB and BA. Q. E. D.

Hence, an object is seen by the reflected ray AB, with the eye placed in A, the same as if the eye were in C, and the object in A.

The truth of this theorem is so easily confirmed by experiment, that some, with Euclid, assume it as a principle, and demonstrate the great law of reflection from it. Thus: suppose the angle of incidence a little greater than the angle of reflection, then will the angle ABF be greater than CBE. Wherefore, changing the places of the eye and the object, the angle CBE will become the angle of incidence; and therefore CBE greater than ABF by the supposition. So that the same angle ABF will be both greater and smaller than the other, CBE; which being absurd, ABF cannot be greater than CBE. The same absurdity will follow, if you suppose the angle of incidence less than the angle of reflection. Since then the angle of incidence can neither be greater nor less than that of reflection, it must be equal to it.

IV. *The plane of reflection, that is, the plane in which the incident and reflected rays, and also the angles of incidence and of reflection, are found, is perpendicular to the surface of the speculum; and in spherical specula, it passes through the centre.*

Hence the cathetus, both of incidence and reflection, is in the plane of reflection.

That the *plane of reflection is perpendicular to the speculum*, is assumed by Euclid, Alhazen, and others, as a principle, without any demonstration; as being evident from all observation and experiment.

V. *The image of an object seen in a mirror is in the cathetus of incidence.* This the ancients assumed as a principle; and hence, since the image is certainly in the reflected ray, they inferred, it must appear in the point of concurrence of the reflected ray, with the cathetus of incidence; which indeed holds universally in plane and spherical mirrors, and usually also in concave ones, a few cases only excepted, as is shewn by Kepler.

For the particular laws of reflection, arising from the circumstances of the several kinds of specula, or mirrors, plane, concave, convex, &c. see them laid down under the article *MIRROR*.

REFLECTION, *Causitic by*. See *Causitic CURVE*.

REFLECTION of *Heat*. See *HEAT*, and *RAYS of Heat*.

REFLECTION of *Gold*. See *COLD*.

REFLECTION of *Sound*. See *SOUND*.

REFLECTION of the *Moon*, is a term used by some authors for what we otherwise call her *variation*, being the third inequality in her motion, by which her true place out of the quadratures differs from her place twice equated. See *MOON and VARIATION*.

REFLECTION is also used, in the Copernican system, for the distance of the pole from the horizon of the disc; which

which is the same thing as the sun's declination in the Ptolemaic system.

REFLECTION is also used figuratively for an operation of the mind, by which, turning as it were back upon itself, it makes itself, and its own operation, its object; and considers or contemplates the manner, order, and laws, which it observes in perceiving, reasoning, willing, judging, doubting, believing, &c. and frames itself new ideas of the relations discovered in them.

REFLECTOIRE CURVE. See CURVE *Reflétoire*.

REFLECTOR for *Light-houses*, a combination of a number of square plane glass mirrors, resembling those with which Archimedes is said to have burnt the Roman fleet at the siege of Syracuse. (See BURNING-Glass.) Each of these mirrors is about an inch square; and they are all arranged close to each other in the concave of a parabolic segment formed of stucco, which has been found to answer the purpose best. The idea of thus illuminating light-houses, instead of using coal-fires, in this country, without any previous knowledge of a similar method practised in France, was first suggested by Mr. Ezekiel Walker, of Lynn Regis, who made, and fixed up reflectors under his direction, in a light-house on the coast of Norfolk, in the year 1779. Accordingly, in the year 1787, at the request of the trustees appointed by act of parliament for erecting four light-houses in the northern parts of Great Britain, he instructed Mr. Thomas Smith, tin-plate worker, of Edinburgh, to whom the original invention is erroneously ascribed in the supplement to the Encyclopædia Britannica, in this mode of constructing light-houses. His parabolic moulds are from three to five or six feet in diameter; and in the centre or apex of each is placed a long shallow lamp of tin-plate, filled with whale-oil. In each lamp are six cotton-wicks, almost contiguous to one another, so disposed as to burn without trimming for six hours. The light of these is reflected from each mirror spread over the concave surface, and is thus multiplied, as it were, by the number of mirrors. The stucco moulding is covered on the back with tin-plate, from which a tube, immediately over the lamp, proceeds to the roof of the light-room, and serves as a funnel, through which the smoke escapes without fudding the faces of the mirrors. The light room is a cupola or lantern of from eight to twelve sides, composed entirely of glass, fixed in cast iron frames or sashes, and roofed with copper. On circular branches passing round the inside of this lantern, at about 18 inches from the glass frames, are placed the reflectors with their lamps, so as that the concave surfaces of two or three of the reflectors front every point of the compass, and throw a blaze of light in all directions. In the roof, immediately over the centre of the room, is a hole, through which pass all the funnels already mentioned, and which serves likewise to admit fresh air to the lamps. This light-room is firmly fixed on the top of a round tower, so as to be immovable by the weather; and the number of the reflectors, and the height of the tower, are less or greater according as it is intended that the light should be seen at a less or a greater distance. Experience, it is said, has obviated several objections to which light-houses of this kind were thought to be liable; and it has been found that light-houses, with lamps and reflectors, are, in every point of view, preferable to those with fires burning in the air. They are supported at a much less expence; their light is more brilliant, and seen at a greater distance, whilst it can never be obscured by smoke, or beaten down, on the lee-side, by a violent gust of wind; and they may be so variously placed, that one light-house cannot be mistaken for another. Besides, the lamps do not need trimming so often

as open fires require fuel, and the man who attends them is never exposed either to cold or wet in the performance of his duty, so that they are less likely to be neglected in stormy weather than those with open fires.

It has been proposed to make the concave surface of the parabola one speculum of metal, instead of covering it over with a number of plain glass mirrors; or to diminish the size of each mirror, if it be thought best to retain them instead of introducing the speculum. To this proposed alteration it has been objected, that the brightest metal does not reflect such a quantity of light as well foliated clear glass; and by diminishing the size of the mirrors, the number of joinings would be increased, in each of which some light is lost, not merely in the seam, but from its being almost impossible to foliate glass perfectly at its edge.

REFLEX, REFLECT, in *Painting*, is understood of those places in a picture which are supposed to be illuminated by a light reflected from some other body represented in the same piece.

Or, reflexes may be defined those places which, beside the general light that illumines the whole piece, receive some particular light from their situation with respect to some more illuminated polished body, that reflects part of the rays it receives upon them.

Reflexes are scarcely sensible, except in the shadowed parts. The management of the reflexes requires great accuracy and skill. All reflected light is supposed to carry with it part of the colour of the body which reflects it; so that those places which receive this light, must have their colour mixed or tinged with that colour. But the same place may receive reflexes from different objects, differently coloured, and those again receive reflexes from others. The painter, therefore, must have a view to every circumstance of the colour, light, and position of each figure; he must consider what effect each has on others, and pursue nature through all the variety of mixtures. See CLAIR-OBSOURE, and LIGHT.

REFLEX *Vision*, or REFLECTED *vision*, is that performed by means of rays reflected from the polished surfaces of objects to the eye.

Reflex vision is the subject of catoptrics. Under reflex vision come all the phenomena of specula or mirrors of all kinds.

REFLEXIBILITY of the *Rays of Light*, is that property by which they are disposed to be reflected. See REFLECTION.

Or, it is their disposition to be turned back into the same medium, from any other medium on whose surface they fall; hence those rays are said to be more or less reflexible, which are returned back more or less easily under the same incidence.

Thus, if light pass out of glass into air, and by being inclined more and more to the common surface of the glass and air, begins at length to be totally reflected by that surface, those sorts of rays which at like incidences are reflected most copiously, or the rays which, by being inclined, begin soonest to be totally reflected, are the most reflexible rays.

That rays of light are of different colours, and endued with different degrees of reflexivity, was first discovered by sir Isaac Newton; and is shewn by the following experiment. Applying a prism DFE (*Plate XVII. Optics, fig. 15.*), whose angles are each 45° , to the aperture C of a darkened room, in such manner as that the light is reflected from the base in G; the violet rays are seen first reflected into HG; the other rays continuing still refracted in IK. After the violet the blue are all refracted, the green, &c.

(See COLOUR.) Hence it appears, that the differently coloured rays differ in degree of reflexibility.

From the other experiments it appears, that those rays which are most reflexible, are also most refrangible. See REFRACTIBILITY.

REFLEXION. See REFLECTION.

REFLEXIVITY, a term employed by Mr. Brougham to denote a property of light, which causes the different rays to be acted upon by bodies, and to begin to be refracted, reflected, inflected, and deflected, at different distances. This property observes the same law with the other optical properties of light; the red ray having most reflexivity, and the violet the least. (See Phil. Trans. for 1797, p. 360.) Mr. Brougham has expressed this property by the three words, "refrangity," "reflexity," and "flexity;" but the power being the same, if such a property exist, different names seem to be unnecessary.

REFLUX of the Sea, the ebbing of the water; or its return from the shore. It is thus called, as being the opposite motion to the flood, or flux. See TIDE.

REFORM, a re-establishment, or revival of former neglected discipline; or a correction of some reigning abuses in it.

The term is much used in a monastic sense, for the reducing an order or congregation of religious to the ancient severity of the rule from which it had gradually swerved; or even for the improving on the ancient rule and institution itself, and voluntarily making it more severe.

In this sense the order of St. Bernard is said to be only a reform of that of St. Benedict.

To REFORM, in a *Military Sense*, is, after some evolution or manœuvre, to bring a line to its natural order, by aligning it on some given point. See BATTALION.

To REFORM, is also to reduce a company, regiment, or other body of men, either by disbanding the whole, or only breaking a part, and retaining the rest; or sometimes by incorporating them with other regiments. Hence,

REFORMADO, or REFORMED *officer*, one whose troop or company is suppressed in a reform, whilst he is continued either in whole or half-pay, doing duty in the regiment. A reformed captain of foot follows the company, and assists the standing officer as a second; but he still maintains his degree and precedence.

REFORMATION, REFORMATIO, the act of reforming, or correcting an error, or abuse, in religion, discipline, or the like.

The reformation of religion, called, by way of eminence, *the Reformation*, was begun by the elector of Saxony, at the solicitation of Luther, about the beginning of the sixteenth century. See LUTHER and LUTHERANISM.

There were many circumstances which concurred at this time to bring about that happy reformation in religion, which rescued one part of Europe from the papal yoke, mitigated its rigour in the other, and produced a revolution in the sentiments of mankind, the greatest as well as the most beneficial that has happened since the publication of Christianity. How far the sale of indulgences, published by Leo X., contributed to this event, we have already shewn under the article LUTHER. We shall here observe, that the same corruptions in the church of Rome which Luther condemned, had been attacked long before his appearance, and the same opinions which he propagated had been published in different places, and supported by the same arguments. Waldus in the 12th century, Wickliffe in the 14th, and Huss in the 15th, had inveighed against the errors of Popery with great boldness, and confuted them with more ingenuity and learning than could have been expected in those illiterate ages in which

they flourished. But all these premature attempts towards a reformation proved abortive. Many powerful causes contributed to facilitate Luther's progress, which either did not exist, or did not operate with full force in their days: the principal of these we shall here enumerate. The long and scandalous schism which divided the church, during the latter part of the 14th, and the beginning of the 15th centuries, had a great effect in diminishing the veneration with which the world had been accustomed to view the papal dignity. The proceedings of the councils of Constance and Basil spread this disrespect for the Romish see still wider, and by their bold exertion of authority in deposing and electing popes, taught the world that there was in the church a jurisdiction superior even to the papal power, which they had long believed to be supreme. The wound given on that occasion to the papal authority was scarcely healed, when the pontificates of Alexander VI. and Julius II. both able princes, but detestable ecclesiastics, raised new scandal in Christendom. Besides, many of the dignified clergy, secular as well as regular, neglected the duties of their office, and indulged themselves, without reserve, in all the vices to which great wealth and idleness naturally give birth; and gross ignorance and low debauchery rendered the inferior clergy as contemptible as the others were odious. So that we find, long before the 16th century, that many authors of reputation give such description of the dissolute morals of the clergy, as seems almost incredible in the present age. The scandal of those crimes, which very generally prevailed, was greatly increased by the facility with which such as committed them obtained pardon. The exorbitant wealth of the church, the vast personal immunities of ecclesiastics, and their encroachments on the jurisdiction of the laity, and their various devices to secure their usurpations, created much dissatisfaction among the people, and disposed them to pay particular attention to the invectives of Luther. Besides these causes of his rapid progress, we may also reckon the invention of the art of printing, about half a century before his time, the revival of learning at the same period, and the bold spirit of inquiry which it excited in Europe; so that many were prepared to embrace his doctrines, who did not really wish success to his undertaking. In the writings of Reuchlin, Hutten, and the other revivers of learning in Germany, the corruptions of the church of Rome are censured with an acrimony of style little inferior to that of Luther himself. The raillery and oblique censures of Erasmus in particular, upon the errors of the church, as well as upon the ignorance and vices of the clergy, prepared the way for Luther's invectives and more direct attacks. To all which we may add, that the theological doctrines of Popery were so repugnant to the spirit of Christianity, and so destitute of any foundation in reason, in the word of God, or in the practice of the church, that this circumstance combined in favouring the progress of Luther's opinions, and in weakening the resistance of his adversaries.

The rise of the reformation in Switzerland was at least as early as in Germany; for Ulrich Zuingli had, in the year 1516, begun to explain the scriptures to the people, and to censure, though with great prudence and moderation, the errors of a corrupt church. He had very noble and extensive ideas of a general reformation, at the time when Luther retained almost the whole system of Popery, indulgences excepted; and he had actually called in question the authority and supremacy of the pope, before the name of Luther was known in that country. In the year 1524, Nuremberg, Francfort, Hamburgh, and several other cities in Germany, of the first rank, openly embraced the reformed religion, and by the authority of their magistrates abolished

REFORMATION.

the mafs, and the other fuperftitious rites of Popery. The elector of Brandenburg, Saxony, the marquis of the landgrave of Hefle, the dukes of Brunfwick and Lunenburgh, and prince of Anhalt, became avowed patrons of Luther's opinions, and countenanced the preaching of them among their fubjects. The reformers derived great advantage from the tranfactions of the diet at Nuremberg, which prefented to the pope a catalogue of a hundred grievances, which the empire imputed to the iniquitous dominion of the papal fee. The progress of the reformation in Germany was likewise promoted by the proceedings of the diet held at Spire in the years 1526 and 1529. See LUTHER and PROTESTANTS.

During these tranfactions in Germany, the dawn of truth arofe upon other nations. The light of the reformation fpread itfelf far and wide; and almoft all the European ftates welcomed its falutary beams, and exulted in the profpect of an approaching deliverance from the yoke of fuperftition and fpiritual defpotifm. Some of the moft confiderable provinces of Europe had already broke their chains, and openly withdrawn themfelves from the difcipline of Rome and the jurifdiction of its pontiff. The reformed religion was propagated in Sweden, foon after Luther's rupture with Rome, by Olaus Petri, one of his difciples, who was countenanced and encouraged by the valiant and public-fpirited prince Guftavus Vafa Ericfon, to whose firmnefs and magnanimity it was owing, that from the year 1527 the papal empire in Sweden was entirely overturned, and Guftavus declared head of the church. The light of the reformation was alfo received in Denmark fo early as the year 1521, in confequence of the ardent defire difcovered by Chriftiern II., for purpofes of mere ambition, of having his difciples instructed in the doctines of Luther. His fucceffor Frederic, duke of Holftain and Silefia, contributed greatly to the progress of the reformation, by his fucceffful attempts in favour of religious liberty, at the afsembly of ftates that was held at Odenfee, in the year 1527, when he procured the publication of the famous edict which declared every fubject of Denmark free, either to adhere to the tenets of the church of Rome, or to embrace the doctrine of Luther; that no perfon fhould be molefted on account of his religion; that a royal protection fhould be granted to the Lutherans; and that ecclefiaftics of every order fhould be allowed to marry. But the honour of accomplifhing this glorious work was referved for Chriftiern III. a prince equally diftinguifhed by his piety and prudence. The religious doctrine, difcipline, and worfhip of this kingdom, were deftroyed according to a plan laid down by Bugenhagenius. And the afsembly of the ftates at Odenfee, in 1539, gave a folemn fanction to all thefe tranfactions, and thus the work of reformation was brought to perfection in Denmark.

In the fame year the reformation was eftablifhed in every part of Saxony. Upon the death of George, duke of Saxony, who was an inveterate enemy to the reformation, the fucceffion fell to his brother Henry, whose attachment to the Proteftant religion furpaffed, if poffible, that of his predecessor to Popery. Henry invited fome Proteftant divines, and among them Luther himfelf, to Leipzig; and by their advice and affiftance, he learned, in a few weeks, the whole fystem of ancient rites, eftablifhing the full exercife of the Proteftant religion, with the univerfal applaufe of his fubjects, who had long wifhed for this change, which the obftinacy of their former duke had alone prevented. This revolution delivered the Proteftants from the danger to which they were expofed by having an inveterate enemy fettled in the middle of their territories; and their dominions now extended in a great and almoft unbroken line from the fouth of the Baltic to the banks of the Rhine

In France, the auspicious patronage of Margaret, queen of Navarre, fifter to Francis I., encouraged feveral pious and learned men, whose religious sentiments were the fame with her own, to propagate the principles of the reformation, and even to erect feveral Proteftant churches in that kingdom. It appears, that, fo early as the year 1523, there were many, and even perfons of rank, and fome of the epifcopal order, who had conceived the utmoft averfion both againft the doctrine and tyranny of Rome. But the wavering and inconfiftent conduct of Francis I. rendered the fituation of the Proteftants in this country always precarious, often diftreffed. Upon the whole, we may obferve, that, before the diet of Augfburg, the doctrine of Luther had made confiderable, though perhaps a fecret, progress in Spain, Hungary, Bohemia, Britain, Poland, and the Netherlands, and had, in all thefe countries, many friends, of whom feveral repaired to Wittemberg to improve their knowledge, and enlarge their views under fuch an eminent mafter. At this diet, held in 1530, the Augfburg or Auguftine confeffion was prefented to the emperor Charles V. and after many debates between the friends of liberty and the votaries of Rome, the latter prevailed; and the diet, in compliance with the opinion and remonftrances of Campeggio, the papal nuncio, iffued a decree, condemning moft of the peculiar tenets held by the Proteftants; forbidding any perfon to protect or tolerate thofe who taught them; enjoining a ftrict obfervance of the eftablifhed rites; and prohibiting any farther innovation, under fevere penalties. Thofe who refufed to obey this decree were declared incapable of acting as judges, or of appearing as parties in the imperial chamber, the fupreme court of judicature in the empire. The Proteftants, alarmed at the feverity of the decree, afsembled at Smalcald, and concluded a league of mutual defence againft all aggreffors, by which they formed the Proteftant ftates of the empire into one regular body: and they refolved to apply to the kings of England, France, and Denmark, to implore them to affift and patronize this new confederacy. After various negociations between the emperor and the Proteftant princes, terms of pacification were agreed upon at Nuremberg, and ratified folemnly in the diet of Ratisbon, in the year 1532. In this treaty it was ftipulated, that univerfal peace be eftablifhed in Germany, until the meeting of a general council, the convocation of which, within fix months, the emperor fhall endeavour to procure; that no perfon be molefted on account of religion; that a ftop be put to all proceffes begun by the imperial chamber againft Proteftants; and the fentences already paffed to their detriment be declared void. On their part, the Proteftants engaged to affift the emperor with all their forces in refifting the invafion of the Turks. Thus the Proteftants, by their firmnefs, unanimity, and dexterity in availing themfelves of the emperor's fituation, obtained terms which amounted almoft to a toleration of their religion. But neither the emperor nor the pope were difpofed to abide by the unbiaffed fense of a general council, afsembled, as the Proteftants wifhed, within the limit of the empire, but determined to decide their religious debates by the force of arms. After many evafions and delays, it was propofed, in the year 1545, to afsemble a council at Trent, which was vigorously oppofed by the Proteftants. The emperor and the pope had mutually agreed to deftroy all who fhould dare to oppofe this council. The meeting of that afsembly was to ferve as a fignal for their taking arms; and accordingly its deliberations were fcarcely begun, in the year 1546, when the Proteftants perceived undoubted marks of a formidable union to overwhelm and crush them by one blow. The fathers, afsembled in the council of Trent, promulgated

REFORMATION.

their decrees; and the Protestant princes in the diet of Ratibon protested against their authority; and were, in consequence of this, proscribed by the emperor, who raised an army to reduce them to obedience. Thus commenced the war of Smalcald, which was prosecuted with various successes on both sides, till, in the year 1552, Charles was surprised at Inspruck by Maurice of Saxony, and was constrained to conclude at Passau the famous treaty of *pacification*, (which see,) with the Protestants, which is considered by those of Germany as the basis of their religious liberty; and to promise in six months to assemble a diet, in which all the tumults and dissensions, that had been occasioned by a variety of sentiments in religious matters, should be entirely removed. This diet, though not assembled at the stipulated time, met, however, at Augsburg, in the year 1555, and terminated those deplorable scenes of bloodshed, desolation, and discord, that had so long afflicted both church and state by that *religious peace*, as it is commonly called, which secured to the Protestants the free exercise of their religion, and established this inestimable liberty upon the firmest foundations. For, after various debates, the following memorable acts were passed; that the Protestants who followed the confession of Augsburg, should for the future be considered as entirely exempted from the jurisdiction of the Roman pontiff, and from the authority and superintendance of the bishops; that they were left at perfect liberty to enact laws for themselves, relating to their religious sentiments, discipline, and worship; that all the inhabitants of the German empire should be allowed to judge for themselves in religious matters, and to join themselves to that church whose doctrine and worship they thought the purest and most consonant to the spirit of Christianity; and that all those, who should injure or persecute any person under religious pretences, and on account of their opinions, should be declared, and proceeded against, as public enemies of the empire, invaders of its liberty, and disturbers of its peace.

In the year 1533, Henry VIII. king of England, who, in the beginning of these troubles, had opposed the doctrine and views of Luther with the utmost vehemence, partly because he had spoken with contempt of Thomas Aquinas, the king's favourite author, having sued for a divorce from Catharine of Arragon, his brother's widow, at the court of Rome, for almost six years, during which period Clement VII. negotiated, promised, retracted, and concluded nothing, determined to apply to another tribunal for that decree which he had unsuccessfully solicited at Rome. Cranmer, archbishop of Canterbury, by a sentence founded on the authority of universities, doctors, and rabbies, who had been consulted with respect to the point, annulled the king's marriage with Catharine; and Anne Boleyn, whose charms had captivated the king, was acknowledged as queen of England. Clement, apprehensive lest England would revolt from the holy see, determined to give Henry such satisfaction as might still retain him within the bosom of the church. But the violence of the cardinals precipitated him, in 1534, to issue a bull rescinding Cranmer's sentence, confirming Henry's marriage with Catharine, and declaring him excommunicated, if, within a time specified, he did not abandon the wife he had taken, and return to her whom he had deserted. Enraged at this unexpected decree, Henry kept no longer any measures with the court of Rome; his subjects seconded his resentment; an act of parliament was passed, abolishing the papal power and jurisdiction in England; by another the king was declared supreme head of the church, and all the authority of which the popes were deprived was vested in him; the *monasteries*, (which see,) were suppressed, and their revenues applied to other purposes.

The people had been gradually prepared for this great innovation. Each succeeding session of parliament had made some retrenchment from the power and profits of the Roman pontiff. Care had been taken, during some years, to teach the nation that a general council was much superior to a pope. But now a bishop preached every Sunday at Paul's Cross, in order to inculcate the doctrine, that the pope was intitled to no authority at all beyond his own diocese.

The laws passed during this session (1534) sufficiently evince, that the king was determined not to surrender any part of his assumed prerogative. All payments made to the apostolic chamber: all provisions, bulls, dispensations, were abolished: monasteries were to be subjected to the regulation and government of the king alone: the law for punishing heretics was moderated: the ordinary was prohibited from imprisoning or trying any person upon suspicion alone, without presentment by ten lawful witnesses: and it was declared that to speak against the pope's authority was no heresy: bishops were to be appointed by a *congé d'elire* from the crown, or, in case of the dean and chapter's refusal, by letters patent; and no recourse was to be had to Rome for palls, bulls, or provisions. Campeggio and Ghinucci, two Italians, were deprived of the bishoprics of Salisbury and Worcester, which they had hitherto enjoyed: the law which had been formerly made against paying annats, or first fruits, but which had been left in the king's power to suspend or enforce, was finally established: and a submission which was exacted two years before from the clergy, and which had been obtained with great difficulty, received this session the sanction of parliament. In this submission, the clergy acknowledged that convocations ought to be assembled by the king's authority only: they promised to enact no new canons without his consent: and they agreed that he should appoint 32 commissioners, in order to examine the old canons, and abrogate such as should be found prejudicial to his royal prerogative. An appeal was also allowed from the bishop's court to the king in chancery. But the most important act passed this session, was that which regulated the succession to the crown: the marriage of the king with Catharine was declared unlawful, void, and of no effect: the primate's sentence annulling it was ratified; and the marriage with queen Anne was established and confirmed. The crown was appointed to descend to the issue of this marriage, and failing there, to the king's heirs for ever. An oath was likewise enjoined to be taken in favour of this order of succession, under the penalty of imprisonment during the king's pleasure, and forfeiture of goods and chattels: and all slander against the king, queen, or their issue, was subjected to the penalty of misprision of treason. These several acts, so contemptuous towards the pope, and so destructive of his authority, were passed at the very time that Clement pronounced his hasty sentence against the king. The king found his ecclesiastical subjects as compliant as the laity. The convocation ordered that the act against appeals to Rome, together with the king's appeal from the pope to a general council, should be affixed to all the doors of all the churches in the kingdom; and they voted that the bishop of Rome had, by the laws of God, no more jurisdiction in England than any other foreign bishop; and that the authority which he and his predecessors had there exercised, was only by usurpation, and by the sufferance of English princes. The bishops went so far in their complaisance, that they took out new commissions from the crown, in which all their spiritual and episcopal authority was expressly affirmed to be derived ultimately from the civil magistrate, and to be entirely dependent on his good pleasure.

REFORMATION.

Henry, however, with the caprice peculiar to his character, continued to defend the doctrines of the Romish church as fiercely as he attacked their jurisdiction. He alternately persecuted the Protestants for rejecting the former, and the Catholics for acknowledging the latter.

Nothing more forwarded the first progress of the reformers, than the offer which they made, of submitting all religious doctrines to private judgment, and the summons given every one to examine the principles formerly imposed upon them. And what can be more just and reasonable? and yet the multitude, says Mr. Hume, were totally unqualified for this undertaking, though they were highly pleased with it. They fancied that they were exercising their judgment, while they opposed to the prejudices of ancient authority more powerful prejudices of another kind. The novelty itself of the doctrines; the pleasure of an imaginary triumph in dispute; the fervent zeal of the reformed preachers; their patience, and even alacrity, in suffering persecution, death, and torments; a disgust at the restraints of the old religion; an indignation against the tyranny and interested spirit of the ecclesiastics:—these motives, says the same historian, whilst, as some may imagine, he is depreciating the principles of the reformation, were prevalent with the people; and by such considerations were men so generally induced, during that age, to throw off the religion of their ancestors. In proportion, says the same author, as the practice of submitting religion to private judgment was acceptable to the people, it appeared, in some respects, dangerous to the rights of sovereigns, and seemed to destroy that implicit obedience on which the authority of the civil magistrate is chiefly founded. When some Englishmen, such were Tindal, Joye, Constantine, and others, retired to Antwerp, through fear of the exertion of the king's authority, they employed themselves in writing English books against the corruptions of the church of Rome; against images, relics, and pilgrims; and they excited the curiosity of men with regard to that question, which is the most important in theology, the terms of acceptance with the Supreme Being. These books, having been secretly conveyed to England, began to make converts every where; but it was a translation of the scriptures by Tindal that was esteemed the most dangerous to the established faith. Against Wolsey, a favourite minister of Henry VIII., it was one article of impeachment, that, by his connivance, he had encouraged the growth of heresy, and that he had protected and acquitted some notorious offenders. Wolsey was succeeded in the office of chancellor by sir Thomas More, who, irritated by polemics, became so superstitiously attached to the ancient faith, that few inquisitors have been guilty of greater violence in their prosecution of heresy. Several persons were not only brought into the courts for heretical offences, such as teaching their children the Lord's prayer in English, for reading the New Testament in that language, or for speaking against pilgrimages; and others were charged with the capital offences of harbouring persecuted preachers, neglecting the facts of the church, and declaiming against the vices of the clergy. Some were tried, condemned, and committed to the flames. Notwithstanding the inconsistent conduct of Henry, his subjects having been encouraged, by his example, to break some of their fetters, were so impatient to shake off all that remained, that in the following reign, under his son Edward VI., with the general applause of the nation, a total separation was made from the church of Rome in articles of doctrine, as well as in matters of discipline and jurisdiction. (See ARTICLES.) In 1553, his death retarded the progress of the reformation; and his sister Mary, who succeeded him, imposed a new the arbitrary

laws and tyrannical yoke of Rome upon the people of England. But the execution of a great number of persons, who were burnt for the Protestant faith in the five years of her persecuting and bloody reign, so alienated the people from Popery, that queen Elizabeth, her sister, found it no hard matter to deliver her subjects from the bondage of Rome, and to establish that form of religious doctrine and ecclesiastical government, which still subsists in England.

The seeds of the reformation were very early sown in Scotland, by several noblemen of that nation, who had resided in Germany during the religious disputes that divided the empire. The first and most eminent opposer of the Papal jurisdiction was John Knox, a disciple of Calvin, who set out from Geneva for Scotland in 1559, and in a little while prevailed with the greatest part of the Scotch nation entirely to abandon the superstitions of Rome, and to aim at nothing less than the total extirpation of Popery. In the following year, *viz.* 1560, the parliament ratified a confession of faith, agreeable to the new doctrines, and passing a statute against the mass, not only abolished it in all the churches, but enacted, that whoever, any where, either officiated in it, or was present at it, should be chastised, for the first offence, with confiscation of goods, and corporal punishment, at the discretion of the magistrate; for the second, with banishment; and for the third, with loss of life. A law was also voted for abolishing the Papal jurisdiction in Scotland; the Presbyterian form of discipline was settled, leaving only at first some shadow of authority to certain ecclesiastics, whom they called superintendants. From that period to the present times the form of doctrine, worship, and discipline, that had been established at Geneva by the ministry of Calvin, has been maintained in Scotland with invincible obstinacy and zeal; and every attempt to introduce, into that kingdom, the rites and government of the church of England, has proved impotent and unsuccessful. See PRESBYTERIANS.

The cause of the reformation in Ireland underwent the same vicissitudes that had attended it in England. When Henry VIII., after the abolition of the Papal authority, was declared supreme head of the church of England, George Brown, a native of England, and a monk of the Augustin order, whom that monarch had created, in the year 1535, archbishop of Dublin, began to act with the utmost vigour, in consequence of this change in the hierarchy. He purged the churches of his diocese from superstition in all its forms, pulled down images, destroyed relics, abolished absurd and idolatrous rites, and, by the influence as well as authority he had in Ireland, caused the king's supremacy to be acknowledged in that nation. Henry shewed soon after, that this supremacy was not a vain title; for he banished the monks out of that kingdom, confiscated their revenues, and destroyed their convents. In the reign of Edward VI. farther progress was made in the reformation, but the accession of Mary retarded it, in consequence of which Brown and other Protestant bishops were deprived of their dignities in the church. When Elizabeth ascended the throne, the Irish were again obliged to submit to the form of worship and discipline established in England.

The reformation had not been long established in Britain, when the Belgic provinces, united by a respectable confederacy which still subsists, withdrew from their spiritual allegiance to the Roman pontiff. The means which Philip II. king of Spain used to obstruct the reformation, promoted it: the nobility formed themselves into an association, in the year 1566, and roused the people; who, under the heroic conduct of William of Nassau, prince of Orange, seconded by the succours of England and France, delivered this state from

from the Spanish yoke: in consequence of which the reformed religion, as it was professed in Switzerland, was established in the United Provinces; and, at the same time, an universal toleration granted to those whose religious sentiments were of a different nature, whether they retained the faith of Rome, or embraced the reformation in another form, provided that they made no attempts against the authority of the government, or the tranquillity of the public.

While Mr. Home attributes the quick and surprising progress of the reformation in part to the late invention of printing, and revival of learning, he denies that reason had any considerable share in opening men's eyes with regard to the impurities of the Romish church; alleging that philosophy had made little progress, at least not till long after the period of the reformation, and that no influence occurs in which argument has ever been able to free the people from that enormous load of absurdity with which superstition has every where overwhelmed them: to which he adds, that the rapid advance of the Lutheran doctrine, and the violence with which it was embraced, prove sufficiently that it owed not its success to reason and reflection. The art of printing, and the revival of learning, he says, forwarded its progress in another manner. By means of that art, the books of Luther and his sectaries, full of vehemence, declamation, and a rude eloquence, were propagated more quickly, and in greater numbers. The minds of men, somewhat awakened from a profound sleep of so many centuries, were prepared for every novelty, and scrupled less to tread in any unusual path which was opened to them. And as copies of the Scriptures, and other ancient monuments of the Christian faith, became more common, men perceived the innovations which were introduced after the first century; and though argument and reasoning could not give conviction, an historical fact, well supported, was able to make impression on their understandings. As the ecclesiastics would not agree to possess their privileges, though ancient and prior to almost every political establishment in Europe, as matters of civil right, which time might render void, but appealed still to a divine right, they thus tempted men to look to their primitive charter, which, with little difficulty, they could perceive to be defective in truth and authenticity. Besides, Luther and his followers, not furnished with opposing the pretended divinity of the Romish church, and displaying the temporal inconveniences of that establishment, proceeded to treat the religion of their ancestors as abominable, detestable, and damnable; foretold by sacred writ itself as the source of all wickedness and pollution. They denominated the pope antichrist, called an communion the scarlet whore, and gave to Rome the appellation of Babylon; expressions which, however applied, were to be found in scripture, and which were better calculated to operate on the multitude than the most solid arguments. Excited by contest and persecution on the one hand, by success and applause on the other, many of the reformers carried to the greatest extremities their opposition to the church of Rome; and in contradiction to the multiplied superstitions with which that communion was loaded, they adopted an enthusiastic strain of devotion, which admitted of no observances, rites, or ceremonies, but placed all merit in a mysterious species of faith, in inward vision, rapture, and ecstacy. The new sectaries, seized with this spirit, were indefatigable in the propagation of their doctrine, and set at defiance all the anathemas and punishments with which the Roman pontiff endeavoured to overwhelm them.

Thus, in terms which appear to us too disparaging, does our historian describe the origin and progress of the reformation; nor does he pay due respect to the principles on which

it was founded, and to the character of the persons who were the principal agents in accomplishing it. We are ready to acknowledge, that the collateral circumstances above recited rendered its advances more rapid and more extensive; but we cannot allow that it did not owe much of its success to reason and reflection. But whatever may be our opinion of the primary causes that produced it, its influence on the minds and manners of mankind, on the state of society in general, and on the interests of liberty, religion, and virtue, has been eminently and extensively beneficial. Luther had no sooner begun to attack the papal supremacy, than the charm, which had bound mankind for so many ages, was broken at once. The human mind, which had long continued as tame and passive, as if it had been taught to believe whatever was taught, and to bear whatever was imposed, roused of a sudden, and became inquisitive, suspicious, and disdainful of the yoke to which it had hitherto submitted. The reformation, wherever it was received, increased that bold and innovating spirit to which it owed its birth. Men who had the courage to overturn a system, supported by every thing which can command respect or reverence, were not to be overawed by any authority, how great or venerable forever. After having been accustomed to consider themselves as judges of the most important doctrines in religion, to examine these freely, and to reject, without scruple, what appeared to them erroneous, it was natural for them to turn the same daring and inquisitive eye to government, and to think of rectifying whatever disorders or imperfections were discovered there. As religious abuses had been reformed in several places, without the permission of the magistrate, it was an easy transition to attempt the redress of political grievances in the same manner. But though the spirit of innovation, that was excited and promoted by the reformation, might in some instances prove the occasion of turbulence and tumult, the good that eventually accrued from its operation far exceeded the partial and temporary evil that resulted from it. The prevalence of this spirit was so general, that it must have been excited by causes that were natural, and of powerful efficacy; and the consequences that flowed from them must have been as important and interesting as the causes that produced them. The kingdoms of Denmark, Sweden, England, and Scotland, and almost one half of Germany, threw off their allegiance to the pope, abolished his jurisdiction within their territories, and gave the sanction of law to modes of discipline and systems of doctrine, which were not only independent of his power, but hostile to it. Nor was this spirit of innovation confined to those countries which openly revolted from the pope; it spread through all Europe, and broke out in every part of it with various degrees of violence. It penetrated early into France, and made such rapid progress, that the number of converts to the opinions of the reformers was so great, their zeal so enterprising, and the abilities of their leaders so distinguished, that they soon ventured to contend for superiority with the established church, and were sometimes on the point of obtaining it. In all the provinces of Germany which continued to acknowledge the papal supremacy, as well as in the Low Countries, the Protestant doctrines were secretly taught, and had gained so many profelytes, that they were ripe for revolt, and were restrained merely by the dread of their rulers from imitating the example of their neighbours, and asserting their independence: hence in Spain and Italy, symptoms of the same disposition to shake off the yoke appeared. The pretensions of the pope to infallible knowledge and supreme power were treated by many persons of eminent learning and abilities with such scorn, or impugned

with such vehemence, that the most vigilant attention of the civil magistrate, the highest strains of pontifical authority, and all the rigour of the inquisitorial jurisdiction, were requisite to check or extinguish it. The defection of so many opulent and powerful kingdoms from the papal see was a fatal blow to its grandeur and power, and produced a very considerable diminution of its revenues. It likewise obliged the Roman pontiffs to adopt a different system of conduct towards the nations which continued to recognize their jurisdiction, and to govern them by new maxims, and with a milder spirit. They became afraid of venturing upon any such exertion of their authority as might alarm or exasperate their subjects, and excite them to a new revolt. Hence it happens, that the popes, from the era of the reformation, have ruled rather by address and management than by authority. They have been obliged not only to accommodate themselves to the notions of their adherents, but to pay some regard to the prejudices of their enemies. In process of time, and before the convulsions which have lately agitated Europe, they sunk almost to a level with the other petty princes of Italy; and they hardly retain any shadow of the temporal power which they anciently possessed. Nevertheless, whilst the reformation has been fatal to the power of the popes, it has contributed to improve the church of Rome both in science and in morals. Many motives have arisen out of the reformation, and the existence of two rival churches, which have served to engage the Catholic clergy to apply themselves to the study of useful science, and to pay a strict attention to the manners of their clergy. In those countries where the members of the two churches have mingled freely with each other, or have carried on any considerable intercourse, either commercial or literary, an extraordinary alteration in the ideas, as well as in the morals, of the Popish ecclesiastics is manifest. The beneficial influence of the reformation has not only been felt by the clergy, and the inferior members of the Roman Catholic church; but it has extended to the see of Rome, and to the sovereign pontiffs themselves, whose character, at a later period, has been very different from that of several of their predecessors. Many of them have been conspicuous for the virtues becoming their high station; and by their humanity, their love of literature, and their moderation, have made some atonement to mankind for the crimes of those who in former times occupied their places. Thus the reformation has eminently contributed to increase purity of manners, to diffuse science, and to inspire humanity. With the progress of the reformation we may also connect a variety of other important benefits, both to individuals and to society; and as they pertain to the investigation of truth and the improvement of science, to the promotion of liberty both civil and religious, to the diffusion of knowledge and virtue, and to the advancement of the best interests of mankind. But the details of the advantages resulting from the reformation to nations and private persons, to religion in general, and genuine Christianity in particular, would far exceed the limits to which we are confined.

See, on the subject of this article, Robertson's Hist. of Charles V. vol. ii. p. 113, &c. vol. iii. p. 44, &c. Motheim's Eccl. Hist. Eng. ed. Svo. vol. iii. Burnet's Hist. of the Reformation, passim. For a comprehensive, and, upon the whole, a just sketch of the predisposing causes, and beneficial consequences of the reformation, we refer the reader to a work which obtained the prize proposed by the National Institute of France, 15th of Germinal, in the year X. viz. "What has been the influence of the reformation by Luther on the political situation of the different states of Europe, and on the progress of knowledge?" The work

is entitled "An Essay on the Spirit and Influence of the Reformation by Luther," by C. Villers. We have two English translations, one by B. Lambert, and the other by James Mill, 8vo. 1805.

REFORMATION, *Right of, Jus reformationis*. is a right which the princes of Germany claim to reform the church in their respective territories; as being invested with the imperial as well as the temporal power.

The *jus reformationis* is annexed to the sovereignty; by this they have the power of conscience, the disposition of ecclesiastical revenues, &c. as they enjoyed the same at the treaty of Munster in 1624.

REFORMATION of Images, in Optics. See ANAMORPHOSIS.

REFORMED Calendar and Church. See the substantives.

REFORMED Officer. See REFORMADO.

REFRACTED ANGLE, in Optics, the angle contained between the refracted ray and the perpendicular.

REFRACTED Dials, are such as shew the hour by means of some refracting transparent fluid. See DIALS, *Refracted*.

REFRACTED Ray, or ray of refraction. See RAY and REFRACTION.

REFRACTED Vision. See VISION.

REFRACTING TELESCOPE. See TELESCOPE.

REFRACTION, REFRACTIO, in Mechanics, the deviation of a moving body from its direct course, by reason of the different density of the medium it moves in; or a flexion and change of determination, occasioned by a body's falling obliquely out of one medium into another of a different density.

Thus a ball A (*Plate XXXVI. Mechanics, fig. 14.*) moving in the air in the line A B, and falling obliquely on the surface of the water C D, does not proceed straight to E, but deviates, or is inflected, to F. Again, if the ball, moving in water in the same line A B, should fall obliquely on a surface of air C D; it will not proceed straight to E, nor yet deflect to F, but to G. Now the deflection in each case is called the *refraction*: and the two cases are distinguished by means of the perpendicular M I; that B G being called *refraction towards the perpendicular*, or to the *axis of refraction*; and the other B F, *refraction from the perpendicular*, or *from the axis of refraction*.

These refractions are supposed to arise hence, that the ball arriving at B, in the first case finds more resistance or opposition on the one side O, i. e. from the side of the water, than it did from the side P, or that of the air; and in the latter more resistance from the side P, which is now the side of the water, than the side O, which is that of the air.

The great law of refraction, then, which holds in all bodies, and all mediums, is that a body, passing obliquely out of a medium which resists it more, is refracted towards the perpendicular; and in passing out of a medium which opposes it less into another which opposes it more, it is refracted from the perpendicular.

Hence the rays of light falling out of air into water are refracted towards the perpendicular; whereas a ball thrown into the water is refracted from it; because water, which resists the motion of light less than air, resists that of the ball more; or, to speak more justly, because water, by its greater attraction, accelerates the motion of the rays of light more than air does; for that this is the true cause of refraction, at least in light, shall be shewn under REFRACTION of light.

To have a body refracted, it is necessary that it should fall obliquely on the second medium. In perpendicular incidence there is no refraction.

REFRACTION.

Vossius indeed, and Snellius, imagined they had observed a perpendicular ray of light undergo a refraction; a perpendicular object appearing in the water nearer than in reality it was; but this was to attribute that to a refraction of the perpendicular rays, which was owing to the divergency of the oblique rays after refraction, from a nearer point.

Yet there is a manifest refraction even of perpendicular rays found in *Island CRYSTAL*, which see.

Rohault adds, that though an oblique incidence be necessary in all other mediums we know of, yet the oblique must not exceed a certain degree; if it do, the body will not penetrate the medium, but will be reflected instead of being refracted.

Thus cannon-balls, in sea-engagements, falling very obliquely on the surface of the water, are observed to mount aloft again, and frequently to sweep the men from off the opposite decks; and the like happens to the little stones with which children make their ducks and drakes.

The ancients confounded refraction with reflection, and it was sir Isaac Newton who first taught us the just difference between them. He shews likewise, that there is a good deal of analogy between them, and particularly in the case of light.

The laws of refraction of the rays of light in mediums differently terminated, *i. e.* whose surfaces are plain, concave, convex, &c. make the subject of *dioptrics*; which see.

By refraction it is, that convex glasses, or lenses, collect the rays, magnify objects, burn, &c. and hence the foundation of microscopes, telescopes, &c.

By refraction it is, that all remote objects are seen out of their real places; particularly, that the heavenly bodies are apparently higher than they are in reality, &c.

The refraction of the air has many times so uncertain an influence on the places of celestial objects, very remote from the zenith, that wherever refraction is concerned, the conclusions deduced from observations that are much affected by it, will always remain doubtful, and too precarious in many cases to be relied upon. See Dr. Bradley, in *Phil. Trans.* N^o 485. See *Atmospherical REFRACTION*.

REFRACTION of Light, in *Optics*, is an inflection or deviation of the rays from their rectilinear course upon falling obliquely out of one medium into another, of a different density.

The term refraction is derived from the distortion which it occasions in the appearance of an object viewed in part only by refracted light; thus, an oar, partially immersed in water, appears to be bent, on account of the refraction of the light, by which its lower part is seen, in its passage out of the water into the air.

Although no sensible light can penetrate more than 700 feet deep into the sea, and a length of seven feet of water has been found to intercept one-half of the light which enters into it; yet in transparent substances (no medium being, strictly speaking, absolutely transparent) the greater part of the light penetrates to all distances with little interruption, and all rays, of the same kind, thus transmitted by the same surface, form with the perpendicular an angle of refraction, which is ultimately in a certain constant proportion to the angle of incidence; that is, for instance, one-half, three-fourths, or two-thirds, according to the nature of the surface. Thus, if the refractive properties of the substance were such, that an incident ray, making an angle of one degree with the perpendicular, would be so refracted as to make an angle of only half a degree with the same line, another ray, incident at an angle of two degrees, would be refracted, without sensible error, into an angle of one degree. But when the angles are larger, they vary

from this ratio, their sines only preserving the proportion with accuracy: for example, if the angle of incidence at the supposed surface were increased to 90°, the angle of refraction would be 30° only, instead of 45°.

It does not appear that, before Descartes, any person attempted to explain the physical cause of the refraction, and also the reflection of light, which he undertook to do by the resolution of forces, on the principles of mechanics: in consequence of which he was obliged to suppose that light passes with more ease through a dense medium than a rare one: thus the ray *A B* (*Plate XVIII. Optics, fig. 10.*) falling obliquely on a denser medium at *B*, is supposed to be acted on by two forces, one of them impelling it in the direction *A C*, and the other in *A D*, which alone can be affected by the change of medium: and since, after the ray has entered the denser medium, it approaches the perpendicular *B H*, it is plain that this force must have received an increase, whilst the other continued the same; for if *B E* be taken equal to *B D*, or *C A*, the consequence of the angle *I B H* being less than *A B C* will be, that *B H* must be longer than *B C* or *A D*.

The first person who questioned the truth of this explanation of the cause of refraction was M. Fermat, who asserted, contrary to Descartes, that light suffers greater resistance in water than in air, and greater in glass than in water; and he maintained that the resistance of different mediums, with respect to light, is in proportion to their densities. M. Leibnitz adopted the same general idea; and they reasoned upon the subject in the following manner. Nature, they say, accomplishes her ends by the shortest methods; light, therefore, ought to pass from one point to another, either by the shortest road, or that in which the least time is required. But it is plain that the line in which light passes, when it falls obliquely upon a denser medium, is not the most direct or the shortest; so that it must be that in which the least time is spent. And, whereas it is demonstrable, that light falling obliquely upon a denser medium (in order to take up the least time possible, in passing from a point in one medium to a point in the other) must be refracted in such a manner, that the sines of the angles of incidence and refraction must be to one another, as the different facilities with which light is transmitted in those mediums; it follows that, since light approaches the perpendicular when it passes obliquely from air into water (so that the sine of the angle of refraction is less than that of the angle of incidence), the facility with which water suffers light to pass through it is less than that of the air; so that the light meets with greater resistance in water than in air. This method of arguing from final causes could not satisfy philosophers. Dr. Smith observes that it agrees only to the case of refraction at a plain surface; and that the hypothesis is altogether arbitrary. If he had endeavoured to accommodate his principle to concave and convex surfaces, as he had once proposed, he would soon have perceived its insufficiency. The easiest way for a ray to pass from a given point in any resisting medium into a vacuum, is in a perpendicular to the refracting surface, this being the shortest way, through any difficulty or resistance whatever; but this being reduced to nothing at the refracting surface, it may then take any other course in vacuo, without any farther difficulty; and, on the contrary, in returning back from the vacuum into the dense medium, it must take the shortest course through the same perpendicular as before. Thus, when the sun shines upon the atmosphere, all his rays should be refracted into lines tending to the centre of the earth, as being the shortest and easiest way through the atmosphere, and then we should see the sun exactly over our heads, in all places and at all times. Such is the strange consequence

REFRACTION.

consequence that follows from an hypothesis so arbitrary.

Dechales, in order to explain the law of refraction, supposes that every ray of light is composed of several smaller rays, which adhere to one another; and that they are refracted towards the perpendicular, in passing into a denser medium, because one part of the ray meets with more resistance than another part; so that the former traverses a smaller space than the latter; in consequence of which the ray must necessarily bend a little towards the perpendicular. This hypothesis was adopted by the famous Dr. Barrow, who, as some say, was the author of it. On this hypothesis, it is plain that mediums of a greater refractive power must give greater resistance to the passage of the rays of light than mediums of a less refractive power, which is contrary to fact.

The Bernouillis, both father and son, have attempted to explain the cause of refraction on mechanical principles; the former on the equilibrium of forces, and the latter on the same principles with the supposition of ethereal vortices; but neither of these hypotheses have gained much credit. M. Mairan supposes a subtle fluid, filling the pores of all bodies, and extending, like an atmosphere, to a small distance beyond their surfaces; and then he supposes that the refraction of light is nothing more than a necessary and mechanical effect of the incidence of a small body in those circumstances. There is more, he says, of the refracting fluid in water than in air, less in water than in glass, and in general less in a dense medium than in one that is rarer. M. de Maupertuis supposes that the course which every ray takes, in passing from one medium into another, is that which requires the least quantity of action, which depends upon the velocity of the body, and the space it passes over; so that it is in proportion to the sum of the spaces, multiplied by the velocity with which bodies pass over them. From this principle he deduces the necessity of the sine of the angle of incidence being in a constant proportion to that of refraction; and also all the other laws relating to the propagation and reflection of light.

Dr. Smith (in his Optics, Remarks, p. 70.) observes, that all other theories for explaining the reflection and refractions of light, except sir Isaac Newton's, suppose that it strikes upon bodies, and is resisted by them, which has never been proved by any deduction from experience. On the contrary, it appears by various considerations, and might be shewn by Mr. Molyneux's and professor Bradley's observations on the parallax of the fixed stars, that their rays are not at all impelled by the rapid motion of the earth's atmosphere, nor by the object-glass of the telescope through which they pass. And by sir Isaac Newton's theory of refraction, which is grounded on experience only, it appears, that light is so far from being resisted and retarded by refraction into any dense medium, that it is swifter there than in vacuo, in the ratio of the sine of incidence in vacuo to the sine of refraction into the dense medium. From some cases of the production of colours, we are led to suppose, says Dr. Young (Lect. Phil. vol. i. p. 460.) that the velocity of light must be smaller in a denser than in a rarer medium; and supposing this fact to be established, the existence of such an attractive force as sir Isaac Newton suggests could no longer be allowed; nor, he says, could the system of the emanation of light, in opposition to that of the undulation of an ethereal medium, be maintained by any one. Priestley's Hist. of Light, &c. p. 102, &c. p. 333, &c.

The refraction of light, sir Isaac Newton shews, is not performed by the very rays falling on the surface of bodies; but it is done without any contact, by the action of some power belonging to bodies, and extending to a certain dis-

tance without their surfaces; by which same power, acting in other circumstances, they are also emitted and reflected.

Admitting that certain powers of attraction and repulsion belong to bodies, and extend to a certain distance beyond their surfaces, and supposing also that light consists of particles emitted from luminous bodies, sir Isaac Newton demonstrates, in his "Principia," that the sine of the angle of incidence must be always to the sine of the angle of refraction in some certain ratio. For, as he proves geometrically, if two similar mediums be separated from each other by a space terminated on both sides by parallel planes, and a body, in its passage through that space, be attracted or impelled perpendicularly towards either of those mediums, and not agitated or hindered by any other force; and if the attraction be every where the same, at equal distances from either plane, taken towards the same hand of the plane, the sine of incidence upon either plane will be to the sine of emergence from the other plane in a given ratio.

In a corollary to this proposition he also shews, that if, instead of one parallel space, bodies be surrounded with several, or an infinite number of them, the attractive power of each of which differs from the next, increasing or decreasing, still, the ratio respecting any two contiguous ones being given, the ratio of the extremes will be given. He also demonstrates, that, if the cause of refraction be the attraction of the refracting medium, the velocity of light before its incidence will be to its velocity afterwards, as the sine of the angle of refraction is to the sine of the angle of incidence; so that light, in passing from a rarer medium into a denser, receives an increase of velocity. The same things being supposed, he shews, that if the velocity before incidence be greater than afterwards, so that the angle of emergence must always increase, in consequence of the repulsive power prevailing over the attractive one, the body will at length be reflected; and that, in this case, the angle of reflection must necessarily be equal to the angle of incidence.

That light does not consist of any mode of action upon a fluid medium, he concludes from having demonstrated that pressure cannot be propagated through a fluid in rectilinear directions, unless where the particles of the fluid lie in a right line, but must diverge into the unmoved spaces; and that every tremulous body, in an elastic medium, propagates the motion of the pulses on every side straight forwards. Admitting this, there is hardly any hypothesis that will agree with the phenomena of light, but that of particles emitted from the luminous body, affected by the attractions and repulsions of other bodies.

The same arguments by which we have proved, that *reflection* (which see) is performed without immediate contact, will go a great way towards demonstrating the same of *refraction*: to which may be added the following ones.

1. Because, if when light falls out of glass into air with the utmost obliquity it will be transmitted at, it be then made to fall a little more obliquely, it becomes wholly reflected: for the power of the glass, after it has refracted light emerging as obliquely as possible, supposing the rays to fall still more obliquely, will be too strong to let any of the rays pass; consequently, instead of being refracted, they will all be reflected.

2. Because in thin lamellæ, or plates of glass, light is reflected and transmitted several times alternately, as the thickness of the lamellæ increases in arithmetical progression; for here it depends on the thickness of the lamina which of the two the glass shall do, whether reflect it, or let it be transmitted.

3. Because, whereas the power of other bodies both to reflect and refract light are very nearly proportional to their densities;

REFRACTION.

densities; yet unctuous and sulphureous bodies are found to reflect more strongly than according to their mere densities: for as the rays act more strongly on those bodies to kindle them than on others, so do they again, by their mutual attraction, act more strongly on the rays to refract them.

Lastly; Because not only those rays transmitted through glass are found to be refracted, but also those passing in the air, or in a vacuum near its extremities, or even near the extremes of many opaque bodies, *e. gr.* the edge of a knife, undergo a similar inflection, from the attraction of the body. See LIGHT, and also INFLECTION.

The manner in which refraction is performed by mere attraction, without contact, may be thus accounted for: suppose HI (*Plate XVIII. Optics, fig. 11.*) the boundary of two mediums, N and O; the first the rarer, *e. gr.* air; the second the denser, *e. gr.* glass; the attractions of the mediums here will be as their densities. Suppose pS to be the distance to which the attracting force of the denser mediums exerts itself within the rarer. Let now a ray of light Aa fall obliquely on the surface which separates the mediums, or rather on the surface pS , where the action of the second and more resisting medium commences. All attraction being performed in lines perpendicular to the attractive body, as the ray arrives at a , it will begin to be turned out of its rectilinear course by a superior force, with which it is attracted by the medium O, more than by the medium N, *i. e.* by a force with which it is driven towards it in a direction perpendicular to its surface: hence the ray is bent out of its right line in every point of its passage between pS and RT , within which distance the attraction acts. Between those lines, therefore, it describes a curve aBb ; but beyond RT , being out of the sphere of attraction of the medium N, it will proceed uniformly in a right line, according to the direction of the curve in the point b .

Again, suppose N the denser and more resisting medium, O the rarer, and HI the boundary, as before; and let RT be the distance to which the denser medium exerts its attractive force within the rarer: even when the ray has passed the point B, it will be within the sphere of superior attraction of the denser medium; but that attraction acting in lines perpendicular to its surface, the ray will be continually drawn from its straight course BM perpendicularly towards HI : thus, having two forces or directions, it will have a compound motion, by which, instead of BM , it will describe Bm , which Bm will in strictness be a curve.

Lastly, after it has arrived in m , being out of the influence of the medium N, it will persist uniformly in a right line, in the direction in which the extreme of the curve leaves it.

Thus we see how refraction is performed, both *towards the perpendicular, and from it.*

But note, the attraction of the denser medium, *e. gr.* N, is continually diminishing, as the ray proceeds from B, towards the limit of attraction RT ; because fewer and fewer parts still come to act; at IH , *e. gr.* all the parts between that and pS attract; but at RT , none but those in the line HI . Note, also, that the distance between pS and RT being small, when we consider refractions, no notice is taken of the curve part of the ray, but we consider it as consisting of two straight lines, CB , AB , or mB , AB .

Sir Isaac Newton, not content with ascribing the reflection, refraction, and inflection of light to powers of attraction and repulsion, extending beyond the surfaces of bodies and producing effect in the manner above explained, proposes a conjecture concerning the physical cause of this attraction and repulsion; but his hypothesis is no less liable to difficulties and objections than the hypothesis of the me-

chanical production of the motion of light without attraction or repulsion. Does not the refraction of light, he says, arise from the different density of an ethereal medium in different places, the light always receding from the denser parts of the medium? And is not the density of it greater in free and open spaces void of air, and other gross bodies, than within the pores of water, glass, crystal, gems, and other compact bodies? For when light passes through glass or crystal, and falling very obliquely upon the farther surface, is all reflected, the total reflection ought to arise rather from the density and vigour of the medium without and beyond the glass, than from the rarity and weakness of it.— Does not the ethereal medium, in passing out of water, glass, crystal, and other compact and dense bodies, into empty spaces, grow denser and denser by degrees, and by that means refract the rays of light, not in a point, but by bending them gradually in curve lines? And does not the gradual condensation of this medium extend to some distance from the bodies, and thereby cause the inflections of the rays of light, which pass by the edges of the dense bodies, at some distance from the bodies?

REFRACTION, in *Dioptrics*, is the inflection or bending of the rays of light, in passing the surfaces of glasses, lenses, and other transparent bodies of different densities.

Thus a ray, as AB (*Plate XVIII. Optics, fig. 11.*) falling obliquely from the radiant A , upon a point B , in a diaphanous surface, HI , rarer or denser than the medium along which it was propagated from the radiant; has its direction there altered by the action of the new medium; and instead of proceeding to M , it deviates, *e. gr.* to C .

This deviation is called the *refraction of the ray*; BC the *refracted ray, or line of refraction*; and B the *point of refraction*.

The line AB is called the *line of incidence, or ray of incidence*; and, in respect of it, B is also called the *point of incidence*.

The plane in which both the incident and refracted rays are found, is called the *plane of refraction*; a right line BE , drawn in the refracting medium perpendicular to the refracting surface, in the point of refraction B , is called the *axis of refraction*; and a right line DB , drawn perpendicular to the refracting surface, in the point of incidence B , along the medium through which the ray fell, is called the *axis of incidence*.

The angle ABI , included between the incident ray and the refracting surface, is called the *angle of incidence*; and the angle ABD , included between the incident ray and the axis of incidence, is called the *angle of inclination*. The angle MCB , which the refracted ray makes with the incident, is called the *angle of refraction*: and the angle CBE , which the refracted ray makes with the axis of refraction, is called the *refracted angle*.

REFRACTION, *general laws of.* 1. *A ray of light in its passage out of a rarer into a denser medium, e. gr. out of air into glass, is refracted towards the perpendicular, i. e. towards the axis of refraction.*

Hence, the refracted angle is less than the angle of inclination; and the angle of refraction less than that of incidence; as they would be equal were the ray to proceed straight from A to M . Hence, also, a ray perpendicular to the refracting surface, will pass through without being refracted, as it cannot be refracted to the perpendicular. The physical cause of which is, that the attraction of the denser medium, which, in an incidence oblique to its surface acts perpendicularly to that surface, draws the ray out of its course: this attraction, we say, in a perpendicular incidence, acts in the direction of the ray.

2. *The ratio of the sine of the angle of inclination, to the sine*

REFRACTION.

sine of the refracted angle, is fixed and constant; viz. if the refraction be out of air into glass, it is found greater than as 114 to 76, but less than 115 to 76; that is, nearly as 3 to 2.

This ratio, assigned by Huygens, agrees with another of Sir Isaac Newton, who makes the sine of the angle of inclination to the sine of the refracted angle, as 31 to 20; which is, likewise, nearly as 3 to 2. Indeed, there is some difference in the quantity of refraction, in different kinds of glass; but in physical matters, preciseness is not necessary. In rain-water, Descartes found the ratio of the sine of the angle of inclination, to the sine of the refracted angle, as 250 to 187, that is nearly as 4 to 3; which agrees with Sir Isaac Newton's observation, who makes it as 529 to 396. In spirit of wine, the same great author makes the ratio as 100 to 73; which is not far from the sesquitercian ratio. In air he makes it as 3201 to 3200; and as to air, he shews, that a ray of light, in traversing quite through the atmosphere, is refracted the same as it would be, were it to pass with the same obliquity out of a vacuum into air of equal density with that in the lowest part of the atmosphere.

See the following table, in which the proportion of the sines which measure the refractions of several bodies; the densities of the bodies, estimated by their specific gravity; and their refractive power, in respect of their densities, are set down in separate columns.

The refracting bodies.	The proportion of the sines of incidence and refraction of yellow light.	The density and specific gravity of the body.	The refractive power of the body in respect of its density.
A pseudo-topaz, being a natural, pellucid, brittle, hairy stone, of a yellow colour	23 to	14	4.27

Newton's Optics, edit. 3. p. 247.

M. Euler the younger, pursuing a scheme suggested by his father for ascertaining the refractive powers of transparent liquors, made use of two Meniscus glasses, which he put together when they were plunged in the fluid, the refractive power of which he wanted to determine: the

edges of these glasses being ground flat, they immediately cohered, so that none of the fluid could escape; and then they might both together be wiped, and used as one object-glass in a long tube, which he could lengthen or shorten at pleasure; and applying an eye-glass to it, the whole observation he had to make was to measure the exact length of his tube, when he could see through it most distinctly a turret, which was at a considerable distance from him. Or, when the focal distance was less than a foot, he only observed, at what distance from a wall the image of an opposite window was the most distinct. Ac. Berlin. 1762, p. 302.

The refractive power of the fluids which he examined in this manner, he expressed in the following tables.

	The sine of the angle of incidence will be to that of refraction as
A ray of light passing from air into	
Distilled water	1.3358
Rain-water	1.3358
Well-water	1.3366
French wine	1.3453
French brandy	1.3603
Ditto a stronger kind	1.3646
Rectified spirit of wine	1.3685
Ditto more highly rectified	1.3706
The white of an egg	1.3685
Distilled vinegar	1.3442
A solution of gum arabic	1.3467
A solution of two scruples of white sugar in an ounce of water	1.3457
A solution of two scruples of rock-salt, in ditto	1.3477
A solution of two scruples of salt of urine, in ditto	1.3400
Oil of Provence	1.4651
Oil of turpentine	1.4822

To unity.

N. B. The rock-salt and the salt of urine were purified by a double crystallization.

	The sine of the angle of incidence will be to that of refraction as
By a second pair of Meniscuses.	
Distilled water	1.3358
Rain-water	1.3358
Well-water	1.3362
French wine	1.3458
French brandy	1.3600
Ditto a stronger kind	1.3618
Spirit of wine rectified	1.3683
Ditto more highly rectified	1.3705
Tea	1.3376
Mineral alkali saturated (I suppose with water)	1.3600
Spirit of nitre	1.4025
A solution of two scruples of Glauber's salt in an ounce of water	1.3430
A solution of two scruples of digestive salt of Sylvius in ditto	1.3454
A solution of two scruples of sal ammoniac in ditto	1.3488
A solution of two scruples of copperas in ditto	1.3395
Oil of tartar per deliquium	1.3917
Oil of Provence	1.4648
Oil of turpentine	1.4822

To unity.

REFRACTION.

The refractive power of some other fluids found by the second pair of Meniscuses, 18th August, 1761, Reaumur's thermometer being 31 degrees above the freezing point.

	The fine of the angle of incidence will be to that of refraction as
A ray of light passing from air into Well-water	1.3351
Four different solutions of nitre, viz.	
Twelve grains of depurated nitre to an ounce of water	1.3380
Twenty-four grains of depurated nitre to an ounce of water	1.3398
Thirty-eight grains of depurated nitre to an ounce of water	1.3450
Thirty-eight grains of depurated nitre to two ounces of water	1.3540
Four different infusions	
of parsley	1.3355
of nutshells	1.3359
of saffron	1.3393
of fish-scales	1.3353
of Zeltzer water	1.3353
of Eger water	1.3358
Anodyne liquor	1.3650
Spirit of camphor	1.3757
Spirit of Saxon sops	1.4088

That the refractive power of these fluids, thus determined by M. Euler, may be more easily compared with Mr. Hauksbee's and Sir Isaac Newton's experiments, he reduced the result of their observations into the following tables, exactly similar to his own.

The refractive power of certain fluids found by Mr. Hauksbee, see his Experiments, p. 292.

	The fine of the angle of incidence will be to that of refraction as
A ray of light passing from air into Water	1.3359
Spirit of honey	1.3359
Spirit of sal ammoniac	1.3377
Oil of amber	1.3377
Spirit of hartshorn	1.3390
Human urine	1.3419
White of an egg	1.3511
Jelly of hartshorn	1.3541
French brandy	1.3626
Spirit of wine	1.3721
Distilled vinegar	1.3721
Gum ammoniac	1.3723
Aqua regia	1.3808
Ditto from aqua fortis and sal ammoniac	1.3964
Aqua fortis	1.4044
Spirit of nitre	1.4076
The crystalline humour of an ox's eye	1.4635
Butter of antimony	1.6831
Oil of vitriol	1.4262
Oil of wax	1.4524
Oil of lavender	1.4960
Oil of rosemary	1.4719
Oil of origanum	1.4770
Oil of ginger	1.4799
Oil of oranges	1.4833
Oil of turpentine	1.4833
Oil of favine	1.4857

The fine of the angle of incidence will be to that of refraction as

Oil of flowers of musk	1.4878
Oil of mint	1.4911
Oil of amber	1.5010
Oil of cummin	1.5088
Oil of fennel	1.5114
Oil of cloves	1.5136
Oil of anise	1.5191
Oil of cinnamon	1.5340
Oil of fassafra	1.5443

The refractive powers of some transparent liquors according to the observations of Sir Isaac Newton. See Optics, p. 247.

	The fine of the angle of incidence will be to that of refraction as
A ray of light passing from air into A yellow pseudo-topaz	1.6429
Air	0.9997
Glass of antimony	1.8889
A selenites	1.4878
Glass	1.5500
Crystal of the rock	1.5620
Island crystal	1.6666
Sal gem	1.5455
Alum	1.4577
Borax	1.4667
Nitre	1.5238
Dantzick vitriol	1.5000
Oil of vitriol	1.4285
Rain-water	1.3358
Gum arabic	1.4771
Spirit of wine well rectified	1.3698
Camphor	1.5000
Olive oil	1.4666
Linseed oil	1.4814
Spirit of turpentine	1.5625
Amber	1.5556
A diamond	2.4390

See Priestley's Hist. of Light, &c. p. 479, &c.

Whence the different refractive power in different fluids arises, is not determined. Sir Isaac Newton shews, that in many bodies, *e. gr.* glass crystal, a selenites, pseudo-topaz, &c. the refractive power is proportionable to their densities; only in sulphureous bodies, as camphor, linseed oil, olive, amber, spirit of turpentine &c. the power is two or three times greater than in other bodies of equal density; yet even these have the refractive power with respect to each other nearly as their densities.

Water has a refractive power in a middle degree between those two kinds of substances, and is, probably, of a middle nature. Salts and vitriols have refractive powers in a middle degree between those of earthy substances and water, and accordingly are composed of those two sorts of substances. Spirit of wine has a refractive power in a middle degree between those of water and oily substances; and accordingly seems to be composed of both, united by fermentation. It appears, therefore, that all bodies seem to have their refractive powers proportional to their densities, or very nearly, excepting so far as they partake of more or less sulphureous oily particles, and thereby have their refractive powers made greater or less. Whence it seems reasonable to attribute the refractive power of all bodies

REFRACTION.

bodies chiefly, if not wholly, to the sulphureous parts with which they abound.

From the observations of M. Euler it appears, that there is no fluid, and probably no transparent substance of any kind, the refractive power of which is less than that of rain-water, or distilled water; and betwixt air and rain-water there is no substance that has an intermediate refractive power.

After rain-water immediately follows well-water; but there are probably as many varieties in its refractive power as there are different wells. We may, however, conclude, that the ratio of refraction from air into well-water is contained between the limits of 1.336 to 1, and 1.337 to 1.

Spirituons liquors have a greater refractive power in proportion to their strength: but the ratio of refraction from air into any spirituons liquor is never less than 1.34, nor greater than 1.37.

There is, probably, no kind of salt, but what, being dissolved in water, increases its refractive power.

The solutions of salt of urine and of vitriol have the least refractive powers, and those of rock-salt and sal ammoniac the greatest; but the ratio of refraction from air into any saline solution, preserving the proportion of one ounce of salt to twelve of water, will be contained between the limits of 1.34 to 1. and 1.35 to 1.

Distilled vinegar, and the solution of gum arabic, have nearly the same refractive power with common French wine; and the refractive power of white of egg is the same as that of rectified spirit of wine.

Mineral alkali saturated, seems to have the same refractive power with very strong brandy.

Spirit of nitre and oil of tartar per deliquium have a medium refractive power between spirituons liquors and oils.

The refractive powers of oils approach the nearest to that of glass, especially oil of turpentine, which had the greatest refractive power of all the fluids on which he had made experiments.

Sir Isaac Newton suspected that different degrees of heat might have some effect on the refractive power of bodies, but his method of determining the general refraction was not sufficiently accurate to ascertain this circumstance; but happily this method of M. Euler's proved to be well adapted to this purpose.

From his experiments made for this purpose, he infers, that the focal distance of a single lens of glass diminishes with the heat communicated to it; and this diminution of the focal distance is not owing to the increase of bulk in the glass by heat; for the effect of this change is both inconsiderable, and of a contrary nature. There can be no doubt, therefore, but that this alteration in the focal distance is owing to a change in the refractive power of the glass itself, which, as well as, probably, that of all other transparent substances, is increased by heat, and diminished by cold.

It may seem surprising that the focal distance of a single lens should decrease with heat, and yet that of the meniscuses filled with any fluid, should increase with heat; but M. Euler observes, that it by no means follows from hence, that these fluids are affected by heat in a manner different from glass; and, after computing the effect of every circumstance of this complex experiment, of the two glasses, and the fluid combined, he concludes, that heat increases the refractive power of water, and of other fluids, as well as that of glass.

He further observes, that as 66 degrees of heat diminished the focal distance $\frac{1}{3}$ th part, 33 degrees ought to have dimi-

nished it $\frac{1}{6}$ th part: whereas the diminution in this case was $\frac{1}{7}$ th. From hence, says he, one may perhaps conclude, that when it is very cold, the same change in the thermometer has a greater effect on the refractive power of the glass than when it is very hot. But he acknowledges that experiments of this kind are not capable of so much precision as one could wish, and that, perhaps in reality, the 66 degrees made a change of $\frac{1}{6}$ th, and the 33 degrees of $\frac{1}{7}$ th; but he imagined that a great number of experiments, made in different temperatures of the air, might decide this question, especially if object-glasses of a very great focal distance were made use of. Ac. Berl. 1762.

The duke de Chaulnes, not satisfied with the methods used by Newton and others for determining the refractive power of glass, proposed another mode of doing it, which is very ingenious, and, when well conducted, promising success. He formed the glass into plates, the surfaces of which were truly plane and parallel, and having placed small objects on each of them, he found, by means of a compound microscope, to which he applied the most exquisite micrometer, the different distances at which they were distinctly visible, and compared them with the thickness of the glass. This, he says, gives the proportion of the sines of the angles of incidence and refraction in that kind of glass directly. In this method he ascertained the mean refractive power of 15 kinds of glass. Ac. Par. 1767. See Priestley's Hist. of Light, &c. p. 483, &c.

Dr. W. H. Wollaston has proposed a new method of examining refractive as well as dispersive powers, by prismatic reflection. This method was suggested by a consideration of Sir Isaac Newton's prismatic eye-glass, the principle of which depends on the reflection of light at the inner surface of a dense refracting medium.

Since the range of inclination, within which total reflection takes place, depends not only on the density of the reflecting prism, but also on the rarity of the medium adjacent to it, the extent of that range varies with the difference of the densities of the two media. When, therefore, the refractive power of one medium is known, that of any rarer medium may be learned, by examining at what angle a ray of light will be reflected from it.

For instance, when any object is laid under a prism of flint-glass, with air alone interposed, the internal angle of incidence at which the visual ray begins to be totally reflected, and at which the object ceases to be seen by refraction, is about $39^{\circ} 10'$; but when the object has been dipped in water, and brought into contact with the glass, it continues visible, by means of the higher refractive power of the water, as far as $57\frac{1}{2}^{\circ}$ of incidence. When any kind of oil, or any resinous cement, is interposed, this angle is still greater, according to the refractive power of the medium employed; and, by cements that refract more strongly than the glass, the object may be seen through the prism, at whatever angle of incidence it is viewed.

In examining the refractive powers of fluids, or of fusible substances, the requisite contact is easily obtained; but, with solids, which can in few instances be made to touch to any great extent, this cannot be effected without the interposition of some fluid, or cement, of higher refractive power than the medium under examination. Since the surfaces of a stratum so interposed are parallel, it will not effect the total deviation of a ray passing through it, and may therefore be employed without risk of any error in consequence.

Thus, resin, or oil of saffaras, interposed between plate-glass and any other prism, will not alter the result.

If, on the same prism, a piece of selenite and another of plate-glass be cemented near each other, their powers may

REFRACTION.

be compared with the same accuracy as if they were both in absolute contact with it.

For such a mere comparison of any two bodies, a common triangular prism is best adapted; but, for the purpose of actual measurement of refractive powers, Dr. Wollaston has preferred the use of a square prism, because, with a very simple apparatus, it shews the sine of refractive power sought, without the need of any calculation.

Let A (*Plate XVIII. Optics, fig. 12.*) be a square or rectangular prism, to which any substance is applied at *b*, and let any ray of light parallel to *cb* be refracted through the prism, in the direction *bdc*.

Then, if *ef* and *ed* be taken proportional to the sines that represent the refractive powers of the prism and of air, *fg*, which is intercepted between *f* and the perpendicular *eg*, will be the corresponding sine to represent the refractive power of the medium *b*. For since *edg* (opposite to *ef*) is the angle of refraction, *efg* (opposite to *ed*) must be equal to the angle of incidence *bdb*; and $ef : fg :: bd : db :: \text{sine of } cbi : \text{sine of } bbd$.

All, therefore, that is requisite for determining the refractive power of *b*, is to find the means of measuring the line *fg*. On this principle, the instrument in *fig. 13* is constructed. On a board, *ab*, is fixed a piece of flat deal *cd*, to which, by a hinge at *d*, is jointed a second piece *de*, 10 inches long, carrying two plane sights at its extremities. At *e* is a second hinge, connecting *ef*, 15.83 inches long; and a third at the other extremity of *ef*, by which *fg* is connected with it. At *i* also is a hinge, uniting the radius *ig* to the middle of *ef*; and then, since *g* moves in a semicircle *egf*, a line joining *e* and *g* would be perpendicular to *fg*.

The piece *cd* has a cavity in the middle of it, so that, when any substance is applied to the middle of the prism *P*, it may continue to rest horizontally on its extremities. When *ed* has been so elevated, that the yellow rays in the fringe of colours (observable where perfect reflection terminates) are seen through the sights, the point *g*, by means of a vernier which it carries, shews by inspection the length of the sign of refraction sought.

The advantages which this method possesses above the usual mode of examining refractive powers, are greater than they may at first sight appear. The usual practice has been, to form two surfaces of the substance under examination, so inclined to each other that the deviation occasioned by them might be measured. The inclination of these surfaces to each other must also be known; and thence the refractive power might be computed. But, in the method here proposed, it is sufficient to have only one surface, and the result is obtained at once, without computation.

The facility of determining refractive powers is consequently such as to render this property of bodies a very convenient test in many philosophical inquiries.

The following table exhibits a series of substances, arranged according to their refractive powers.

	Iceland spar, strongest	1.657
	Sulphate of barytes (double)	1.646
	Balsam of Tolu	1.60
	Guaiacum	1.596
	Benzoin	—
	Flint glass	1.586
	Ditto	1.583
	Horn	—
	Phosphorus	1.579
	Mica	—
	Opium	—
	Amber	1.547
	Rock crystal (double)	1.547
	Old plate-glass	1.545
	Colophony	1.543
	Box-wood	—
	Bees-wax	1.542
	Oil of saffras	1.536
	Red sealing-wax	—
	Spermaceti, cold	—
	Sugar, after fusion	—
	Arteniate of potash	—
	Mastic	—
	Elemi	—
	White wax (cold)	—
	Oil of cloves	1.535
	Copal	1.535
	Anime	1.535
	Radcliffe crown-glass	1.533
	Pitch	—
	Centre of crystalline of fish, and dry crystalline of an ox	1.530
	Canada balsam	1.528
	Crown glass, common	1.525
	Selenite	1.525
	Caoutchouc	1.524
	Gum lac	—
	Dutch plate-glass	1.517
	Human cuticle	—
	Gum arabic	1.514
	Balsam of capivi	1.507
	Oil of amber	1.505
	English plate-glass	1.504
	French plate-glass	1.500
	Oil of nutmeg	1.497
	Sulphate of potash	1.495
	Tallow, cold	1.49
	Iceland spar, weakest	1.488
	Camphor	1.487
	Linseed oil	1.485
	Butter, cold	1.480
	Essence of lemon	1.476
	Oil of turpentine, common	1.476
	Oil of turpentine, rectified	1.470
	Oil of almonds	—
	Oil of olives	1.469
	Oil of peppermint	1.468
	Oil of lavender	1.467
	Tallow, melted	1.460
	Alum	1.457
	Spermaceti, melted	1.446
	Crystalline lens of an ox	1.447
	to	1.380
	Computed average of ditto	1.430
	Sulphuric acid	1.435
	Fluor spar	1.433
	Nitric acid (sp. gr. 1.48)	1.410
	Alcohol	—
Diamond	2.44	
Plumbago	—	
Native sulphur (double)	2.04	
Glass, consisting of lead 6 and sand 1	1.987

From the law laid down in the beginning of this article, it follows, that one angle of inclination, and its corresponding refracted angle, being found by observation, the refracted angles, corresponding to the several other angles of inclination, are easily computed. Now, Zahnus and Kircher have found, that if the angle of inclination be 70° , the refracted angle will be $38^\circ 50'$; on which principle Zahnus has constructed a table of refractions out of air into glass, for the several degrees of the angle of inclination; a specimen of which follows:

Angle of Inclination.	Refracted Angle.		Angle of Refraction.	
	o	l	o	l
1	0	40	5	0

				20

Hence it appears, that if the angle of inclination be less than 20° , the angle of refraction out of air into glass is almost one-third of the angle of inclination; and, therefore, a ray is refracted to the axis of refraction, by almost a third part of the quantity of its angle of inclination. And on this principle it is that Kepler, and most other dioptrical writers, demonstrate the refractions in glasses; though in estimating the law of these refractions, he followed the example of Alhazen and Vitellio, and sought to discover it in the proportion of the angles, and not in that of the sines.

The true law of refraction was first discovered by Willebrord Snellius, professor of mathematics at Leyden; who found by experiment that the secants of the complements, or co-secants, of the angles of incidence and refraction, are always in the same ratio. It is vulgarly attributed, however, to Descartes; who having seen it in Snellius's MS., first published it in his Dioptrics, without naming Snellius; as we are informed by Huygens. The form in which Descartes gives this law is different from that of Snellius, and in general more commodious; but it might have been easily deduced from it. According to him, the sine of the angle of refraction always bears the same proportion to the sine of the angle of incidence. Indeed, as the rays of light are not all of the same degree of refrangibility, this constant ratio must be different in different kinds. The ratio, therefore, observed by authors, is to be understood of rays of the mean refrangibility, *i. e.* of green rays. The difference of refraction between the least and most refrangible rays, that is, between violet and red rays, Sir Isaac Newton shews is about the $27\frac{1}{2}$ th part of the whole refraction of the mean

refrangible; which difference he owns is so small, that there seldom needs to be any regard paid to it.

3. When a ray passes out of a denser into a rarer medium, *e. gr.* out of glass into air, it is refracted from the perpendicular, or from the axis of refraction. And hence the angle of refraction is greater than the angle of inclination.

Hence, also, if the angle of inclination be less than 30° , M B C (*Plate XVIII. Optics, fig. 11.*) is nearly equal to one-third of M B E; therefore M B C is one-half of C B E; consequently, if the refraction be out of glass into air, and the angle of inclination less than 30° , the ray is refracted from the axis of refraction by almost one-half part of the angle of inclination. And this is the other dioptrical principle used by most authors after Kepler, to demonstrate the refraction of glasses.

If the refraction be out of air into glass, the ratio of the sine of inclination to the sine of the refracted angle is as 3 to 2, or, more accurately, as 17 to 11; if out of air into water, as 4 to 3: therefore, if the refraction be the contrary way, *viz.* out of glass or water into air, the ratio of the sines, in the former case, will be as 2 to 3, or 11 to 17, and in the latter as 3 to 4.

Hence, if the refraction be from water or glass into air, and the angle of incidence or inclination be greater than about $48\frac{1}{2}^\circ$ in water, or greater than about 40° in glass, the ray will not be refracted into air, but will be reflected into a line, which makes the angle of reflection equal to the angle of incidence; because the sines of $48\frac{1}{2}^\circ$ and 40° are to the radius as 3 to 4, and as 11 to 17 nearly, and therefore when the sine has a greater proportion to the radius than as above, the ray will not be refracted.

4. A ray falling on a curve surface, whether concave or convex, is refracted after the same manner as if it fell on a plane which is a tangent to the curve in the point of incidence.

For the curve and plane surface touching it, have an infinitely small part common to them both (each being originally generated by the flux of a point). But a ray is refracted in such a little part; therefore it is the same as if it were refracted in such a plane.

5. If a right line E F (*Plate XVIII. Optics, fig. 14.*) cut a refracting surface, G H, at right angles; and if, from any point in the denser medium, as D, be drawn D C parallel to the incident ray A B: this will meet the refracted ray in C; and will be to it as the sine of the refracted angle to the sine of the angle of inclination.

For $o = x$; but if B C pass out of a denser medium into a rarer, $y > x$; and out of a rarer into a denser, $y < x$; therefore, in the former case, $y > o$, in the latter $y < o$; consequently, in the former, $o + u < y + u$; in the latter $y + u < o + u$. But in the one case $o + u$, and in the other $y + u$, are equal to two right angles; therefore, $o + u$ in this, and $y + u$ in the other, are less than two right angles, and consequently D C will meet B C. But since $o = x$, or the angle of inclination, and y is the refracted angle, it is evident that C B is to C D as the sine of the angle o to the sine of the angle y , or in the ratio of the sine of the angle of inclination to the sine of the refracted angle.

Hence, if B C pass out of glass into air, it is in a subsecquialterate ratio to C D; if, on the other hand, it pass out of air into glass, it is in a sesquialterate ratio to C D.

Hence, also, if light pass out of water into air, C B is in a subsecquitercian ratio to C D; if out of air into water, in a sesquitercian. See figs. 14 and 15.

REFRACTION in plane surfaces, laws of. 1. If parallel rays be refracted out of one transparent medium into another of a dif-

REFRACTION.

a different density, they will continue parallel after refraction. The physical reason is, that, being parallel, their obliquity, or angle of incidence, is the same; but, at equal obliquities, we have shewn the refraction is equal; consequently the parallelism, which they had before the refraction, will be retained after it.

But this may be also demonstrated geometrically: thus, if the rays be perpendicular to the refracting surface, they will pass without any refraction; consequently being parallel before their passage, they will be so after it. If they fall obliquely, as AB and CD (*fig. 16.*), the angles of incidence o and u , and, consequently, also the angles of inclination x and y , will be equal. But the sines of the angles of inclination x and y have the same ratio to the sines of the refracted angles m and n ; therefore the refracted angles m and n , and also the angles s and r , are equal; consequently the refracted rays are parallel.

Hence a glass, plane on both side, being turned directly to the sun, the light passing through it will be propagated after the same manner as if the glass were away; for the rays being perpendicular, will pass without refraction. If the glass be turned obliquely to the sun, the light, after refraction, will be of the same intensity as before, the intensity depending on the spissitude or closeness of the rays, and on the angle with which they strike the object, or the eye; both which are here unvaried.

2. If two rays DC and CP (*fig. 17.*) proceeding from the same radiant C , and falling on a plane surface of a different density, so that the points of refraction D and P are equally distant from the cathetus of incidence GK , the refracted rays DF and PQ have the same virtual focus, or the same point of dispersion G .

Hence, 1. Since, in rays very near each other, the distance from the cathetus is the same as to sense, very near rays will diverge from the same point G , *i. e.* they will have the same virtual focus G .

And hence, 2. When refracted rays, falling on the eye placed out of the cathetus of incidence, are either equally distant from the cathetus, or very near each other, they will show upon the eye, as if they came to it from the point G ; consequently the point C will be seen by the refracted rays as in G .

3. If a ray CD fall obliquely out of a thinner into a denser medium, having a plane surface, the distance of the radiant point CK will have a less ratio to the distance of the point of dispersion, or virtual focus, KG , than the sine of the refracted angle to the sine of the angle of inclination. But if the distance of the point of refraction, from the cathetus of incidence KD , be less than the eleventh or nineteenth part of the distance of the radiant point CK ; and if in the former case the tenth, and in the latter the hundredth, part of it be so small, that it cannot be assigned, or need not be minded, then will CK be to KG , as to sense, in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

Hence, 1. If the refraction be out of air into glass, the distance of the point of dispersion of rays near the cathetus is sesquialterate of the radiant point; of more remote rays greater than sesquialterate. But if the refraction be out of air into water, the distance of the same point will be sesquitercian, when the rays are near the cathetus; and when more remote, greater than sesquitercian.

Hence, 2. If the eye be placed in a dense medium, objects in a rarer will appear more remote than they are; and the place of the image, in any given case, may be determined from the ratio of the refraction. *Thus, to fishes swimming under*

water, objects out of the water must appear farther distant than in reality they are.

4. If a ray DG fall obliquely out of a denser into a rarer medium AB , the distance of the radiant point GK has a greater ratio to the distance of the point of dispersion KC , than the sine of the refracted angle has to the sine of the angle of inclination. In the other case of the preceding theorem, KG will be to KC , as to sense, in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

Hence, 1. If the refraction be out of glass into air, the distance of the point of dispersion of the rays near the cathetus of incidence is subsequalterate of the distance of the radiant point; that of the more remote rays is less than subsequalterate.

But, 2. If the refraction be out of water into air, the distance of the point of dispersion of rays near the cathetus is subsequitercian; of those more remote, less than subsequitercian.

And, 3. The eye, therefore, being placed in a rarer medium, objects, placed in a denser, appear nearer than they are; and the place of the image may be determined in any given case by the ratio of refraction. Hence, the bottom of a vessel full of water is raised by refraction to a third part of its height, with respect to an eye perpendicularly over the refracting surface; and hence *fishes, and other bodies under water, appear nearer than they really are.*

5. If the eye be placed in a rarer medium, an object seen in a denser medium, by a ray refracted in a plane surface, will appear larger than it really is. If the object be in a rarer, and the eye in a denser medium, the object will appear less than it is. And, in each case, the apparent magnitude is to the real one in a ratio compounded of the distance of the point to which the rays tend before refraction, from the refracting surface DE (*fig. 18.*) to the distance of the eye GL from the same, and of the distance GM of the object AB from the eye, to its distance FM from a point F , to which the rays tend before refraction.

Hence, 1. If the object AB be very remote, FM will be physically equal to GM ; and, therefore, the real magnitude MB is to its apparent one MH , as GL to FL , or the distance of the eye G from the refracting plane to the distance of the point of convergence F from the same plane.

Hence, 2. *Objects under water, to an eye in the air, appear larger than they are; and to fishes under water, objects in the air appear less than they are.*

REFRACTION, *Larus of, in spherical surfaces, both concave and convex.* 1. A ray of light DE (*fig. 19.*) parallel to the axis of a denser sphere, after a single refraction in E , falls in with the axis in the point F , beyond the centre C .

For the semidiameter CE , drawn to the point of refraction E , is perpendicular to the surface KL , and is therefore the axis of refraction; but a ray out of a rarer into a denser medium, we have shewn, is refracted towards the perpendicular, or the axis of refraction; therefore the ray DE will converge to the axis of the sphere AF ; and will, therefore, at length concur with it, and that beyond the centre C , in F ; because the angle of refraction FEH is less than the angle of inclination CEH .

2. If a ray DE fall on a spherically convex surface of a denser medium, parallel to its axis AF ; the semidiameter CE will be to the refracted ray EF in the ratio of the sine of the angle of refraction, to the sine of the angle of inclination; but the distance of the focus, or point of concurrence from the centre C F , is to the refracted ray FE , in the ratio

REFRACTION.

ratio of the sine of the refracted angle, to the sine of the angle of inclination.

3. If a ray DE fall on a denser spherical convex surface KL , parallel to the axis AF , the distance of the focus from the refracting surface FB must be to its distance from the centre FC , in a ratio greater than that of the sine of the angle of inclination, to the sine of the refracted angle. But if the rays be very near the axis, and the angle of inclination BCE be only of a few degrees, the distances of the focus from the surface, and the centre, FB and FC , will be nearly in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

Hence, 1. If the refraction be out of air into glass; in the case of rays near the axis, $BF : FC :: 3 : 2$. And in the case of rays remote from the axis, $BF : FC > 3 : 2$. Consequently, in the former case, $BC : BF :: 1 : 3$; and in the latter, $BC : BF < 1 : 3$.

And, 2. If the refraction be out of air into water; in the former case, $BF : FC :: 4 : 3$; and in the latter, $BF : FC > 4 : 3$. Consequently, in the former, $BC : BF :: 1 : 4$; and in the latter, $BC : BF < 1 : 4$.

Hence, 3. Since the sun's rays are parallel as to sense, if they fall on the surface of a solid glass sphere, or of a sphere full of water, they will not concur with the axis within the sphere; so that Vitellio was mistaken, when he imagined, that the sun's rays, falling on the surface of a crystalline sphere, were refracted to the centre.

4. If a ray DE (*fig. 20.*), parallel to the axis FA , fall out of a denser into a rarer spherical medium, after refraction, it will diverge from the axis; and the distance of the point of dispersion, or the virtual focus from the centre of the sphere FC , will be to its semi-diameter CE in the ratio of the sine of the refracted angle, to the sine of the angle of refraction; but to the portion of the refracted ray drawn back, FE , it will be in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

5. If a ray ED fall parallel to the axis AF on the spherically convex surface KL of a rarer medium, out of a denser, the distance of the point of dispersion from the centre FC , is to its distance from the surface FB , in a ratio greater than that of the sine of the refracted angle to the sine of the angle of inclination. But if the rays DE be very near the axis FA , the ratio will be very nearly the same with that of the sine of the refracted angle to the sine of the angle of inclination.

Hence, 1. If the refraction be out of glass into air, in the case of rays near the axis, $FC : FB :: 3 : 2$. Consequently $BC : FB :: 1 : 2$. Therefore, in the case of rays more remote from the axis, $FC : FB > 3 : 2$.

2. If the refraction be out of water into air; in the former case $FC : FB :: 4 : 3$. Consequently, $BC : FB :: 1 : 3$; in the latter case therefore, $FC : FB > 4 : 3$.

3. Since then the point of dispersion F is more remote from the refracting surface KL , if the rays proceed out of water, than if they pass out of glass into air; parallel rays are less dispersed in the former case than in the latter.

6. If a ray HE (*fig. 19.*) fall parallel to the axis FA , out of a rarer, on the surface of a spherically concave denser medium; the refracted ray EN will be driven from the point of the axis F ; so that FE will be to FC in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

7. If a ray EH fall parallel to the axis FB on the concave surface KL of a spherical denser medium, from a rarer; the distance of the point of dispersion from the refracting surface FB , is to its distance from the centre FC ,

in a ratio greater than that of the sine of the angle of inclination, to the sine of the refracted angle. But if the rays be very near the axis, and the angle BCE be very small, BF will be to CF very nearly in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

Hence, 1. If the refraction be out of air into glass; in the case of rays near the axis, $FB : FC :: 3 : 2$; in the case of rays more remote from the axis, $FB : FC > 3 : 2$; consequently, in the former, $BC : FC :: 1 : 2$. And hence, in the latter, $BC : FC < 1 : 2$.

Hence also, 2. If the refraction be out of air into water; in the case of rays near the axis, $FB : FC :: 4 : 3$. In the case of rays more remote from the axis, $FB : FC > 4 : 3$; consequently, in the first case, $BC : FC :: 1 : 3$. And hence, in the latter, $BC : FC > 1 : 3$.

And hence, 3. Since the point of dispersion F is farther from the centre C , if the refraction be in water than in air; rays will be less dispersed in the latter case than in the former.

8. If the ray HE (*fig. 20.*) fall parallel to the axis AF , from a denser upon the surface of a spherical concave rarer medium, the refracted ray will concur with the axis AF , in the point F ; so that the distance of the point of concurrence from the centre CF , may be to the refracted ray FE , in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

9. If a ray HE fall parallel to the axis AF on the concave surface of a rarer medium out of a denser, the distance of the focus from the centre FC will be to its distance from the refracting surface FB in a greater proportion than the sine of the refracted angle, to the sine of the angle of inclination. But if the rays be very near the axis, FC will be to FB in the proportion of these sines.

Hence, 1. If the refraction be out of glass into air; in the case of rays near the axis, $FC : FB :: 3 : 2$; in the case of rays more remote from the axis, $FC : FB > 3 : 2$. Whence, in the former case, $BC : FB :: 1 : 2$.

2. If the refraction be out of water into air; in the case of rays near the axis, $FC : FB :: 4 : 3$; in the case of rays more remote, $FC : FB > 4 : 3$. Whence, in the former case, $BC : FB :: 1 : 3$. For the demonstration of these several laws of refraction, we refer to Wolsius's *Elem. Mathes. &c.* tom. iii. p. 179, &c. See also LENS.

REFRACTION in a glass prism. If a ray of light DE (*fig. 21.*) fall obliquely out of air on a prism ABC ; being refracted towards the perpendicular, instead of proceeding to F , it will decline to G , *i. e.* towards a line HI , drawn perpendicular to the surface AB in the point of refraction E . Again, since the ray EG , passing out of the glass into air, falls obliquely on CB , it will be refracted to M , so as to recede from the perpendicular NGO . *And hence arise the various phenomena of the prism.* See COLOUR and REFRACTIBILITY.

REFRACTION in a convex lens. If parallel rays, AB, CD , and EF (*fig. 22.*) fall on the surface of a lens $2B3K$, the perpendicular ray AB will pass unrefracted to K , where emerging into air perpendicular, as before, it will proceed straight to G . But the rays CD and EF , falling obliquely out of air into glass, in D and F , will be refracted towards the axis of refraction (*i. e.* towards lines HI and LM , drawn perpendicular to the refracting surface in the points of refraction D and F) and decline to Q and P . Again, emerging obliquely out of the glass into the surface of the air, they will be refracted from the perpendicular, and, therefore, DQ will not proceed to X , but to G ; and FP , not to V , but to G ; thus, likewise, might all the other rays, falling on

REFRACTION.

the surface of the glass, be shewn to be refracted so as to meet the rest about the point G. See FOCUS and LENS.

Hence the great property of convex glasses; *viz. that they collect parallel rays, or make them converge into a point.*

REFRACTION in a concave lens. Parallel rays A B, C D, and E F (*fig. 23.*) falling on a concave lens G B H I M K, the ray A B, falling perpendicular on the glass at B, will pass unrefracted to M; where being still perpendicular, it will pass into the air without refraction, to L. But the ray C D, falling obliquely on the surface of the glass, will be refracted towards the perpendicular N D O, and proceed to Q; and the ray D Q, again falling obliquely out of the glass upon the surface of air, will be refracted from the perpendicular R Q S, and proceed to V. After the same manner might the ray E F be shewn to be refracted to Y, and thence to Z.

Hence the great property of concave glasses; *viz. that they disperse parallel rays, or make them diverge.* See LENS and MIRROR.

REFRACTION in a plane glass. If parallel rays E F, G H, I L (*fig. 24.*) fall obliquely on a plane glass A B C D, the obliquity being the same in all, by reason of their parallelism, they will be all equally refracted towards the perpendicular; and accordingly, being still parallel at M, O, and Q, they will pass out into the air equally refracted again from the perpendicular, and still parallel.

Thus will the rays E F, G H, and I L, at their entering the glass, be inflected towards the right; and in their going out as much inflected to the left; so that the first refraction is here undone by the second; and though not so as that the object is seen in its true place. For the ray B Q, being produced back again, will not coincide with the ray L I, but will fall to the right of it; and this the more as the glass is thicker; however, as to matter of colour, the second refraction does really undo the first. See COLOUR.

REFRACTION of Heat. See HEAT, LIGHT, and RAYS of Heat.

REFRACTION in Iceland or Island crystal. See ICELAND CRYSTAL. Dr. Young, who maintains that radiant light consists in undulations of the luminiferous ether, takes occasion to make some remarks on sir Isaac Newton's theory of the peculiar refraction in Iceland crystal. Newton, he says, has advanced the singular refraction of the Iceland crystal, as an argument that the particles of light must be projected corpuscles; since he thinks it probable that the different sides of these particles are differently attracted by the crystal, and since Huygens has confessed his inability to account, in a satisfactory manner, for all the phenomena. But contrarily to what might have been expected from Newton's usual accuracy and candour, he has laid down a new law for the refraction, without giving a reason for rejecting that of Huygens, which Mr. Haüy has found to be more accurate than Newton's; and, without attempting to deduce from his own system any explanation of the more universal and striking effects of doubling spars, he has omitted to observe, that Huygens's most elegant and ingenious theory perfectly accords with these general effects, in all particulars, and of course derives from them additional pretensions to truth; this he omits, in order to point out a difficulty for which only a verbal solution can be found in his own theory, and which will probably long remain unexplained by any other.

Dr. Wollaston, in his paper on the oblique refraction of Iceland crystal, confirms the experiments of Huygens on this substance, with additional evidence, deduced from the superiority of his mode of examining the powers of refraction. He observes that Dr. Young has already applied

the Huygenian theory with considerable success to the explanation of several other optical phenomena, and that it appears to be strongly supported by such a coincidence of the calculations deduced from it, with the results of these experiments, as could have scarcely happened to a false theory.

In ordinary cases, the incipient undulations are of a spherical form; but in the Iceland crystal light appeared to Huygens to proceed as if the undulations were portions of an oblate spheroid, of which the axis is parallel to the short diagonal of an equilateral piece of the crystal, and its centre the point of incidence of its ray. From this spheroidal form of the undulations, he deduces the obliquity of refraction; and lays down a law observable in all refractions, at any surface of the spar, whether natural or artificial, which bears the closest analogy to that which obtains, universally, at other refractory surfaces; for as, in other cases, the ratio is given between the sine of incidence and sine of refraction, (or ordinate of the spherical undulation propagated,) so in the Iceland crystal, the ratio between the sine of incidence and ordinate of refraction (in any one section of the spheroidal undulation) is a given ratio, but different in different planes.

Dr. Wollaston observes, that though we do not fully understand the existence of a double refraction, and are utterly at a loss to account for the phenomena occurring upon a second refraction, by another piece of the spar, yet that the oblique refraction, when considered alone, is nearly as well explained as any other optical phenomenon. Phil. Transf. for 1801 and for 1802.

REFRACTION, Particular laws of, in different kinds of lenses; see LENS.

REFRACTION, Atmospheric, is generally considered under two distinct heads; *viz.* astronomical refraction, which is that relating to the refraction of the moon, stars, and other celestial bodies; and terrestrial refraction, or that which takes place in terrestrial observations.

It appears, from the article REFRACTION, that a ray of light is refracted in passing obliquely out of one medium into another of different density; and as the atmosphere may be considered as composed of an infinitude of strata, whose density increase as they are posited nearer the earth, the luminous rays which pass through it are acted on as if they passed successively through media of increasing density, and are therefore inflected more and more towards the earth, as the density augments, that is, as they approach the eye of the observer. In consequence of this it is, that rays from objects, whether celestial or terrestrial, proceed in curves which are *concave* towards the earth; and since the mind always refers the place of objects to the direction in which the rays reach the eye, that is, to the direction of the tangent to the curve at that point, it follows, that the apparent or observed elevation of objects is always greater than the true one, at least with the exception of some few remarkable anomalies which sometimes, in terrestrial observations, produce a contrary effect, and of which we have stated a few particular instances under the article MIRAGE, and on which subject some other curious facts are recorded in a memoir of professor Vince's, in the Phil. Transf.; in Nicholson's Philosophical Journal, 4to.; and more particularly by M. Monge, in vol. i. of the "Decade Egyptienne." Referring the reader therefore to those works, to which we ought also to add the memoir by M. Biot, in vol. x. of the National Institute, for an account and explanation of those phenomena, we shall confine our present observations to those cases only, in which an uniform law is supposed to have place, and which, as we have seen, has a constant tendency to augment the observed altitude of both terrestrial and celestial objects.

REFRACTION.

objects. In order to submit the phenomena of refraction to strict mathematical investigation, it must be observed that, in consequence of the inconsiderable height of the atmosphere, and its spherical form, a luminous ray impinging upon it, even in the most unfavourable case, that is directly in the horizon, traverses only a small quantity of this medium; and in this space, if the atmosphere is calm, the density of the air at equal heights above the level of the sea is every where the same. Therefore, in supposing the earth spherical, a supposition which may be admitted, in the present case, without any sensible error, we may consider the atmosphere as composed of successive spherical concentric shells, or strata, of which the density diminishes from the surface of the earth upwards.

Let us conceive, now, a luminous ray, coming from a distance, to penetrate into one of the supposed spherical shells; then, if through the common centre of these shells, which is the same as the centre of the earth, we suppose a plane to pass in the direction of the luminous ray, the spherical beds of the atmosphere will be found divided into two equal portions, which acting equally upon the ray, can produce no deviation of it from that plane; whence it follows, that the effect of refraction is entirely produced in a vertical direction, and in such a manner as to augment the apparent altitudes of the heavenly bodies, and consequently to diminish their zenith distances.

But the intensity of these effects will not be the same at all heights, for we know that in all cases the quantity of refraction depends upon the obliquity of incidence, and therefore the refraction in the zenith is equal to zero, and increases from that point to the horizon, where it is the greatest.

If, now, we knew the law by which the density of the air is diminished in ascending from the earth, that is, if we knew the difference in the density of any two consecutive strata, it would be comparatively a direct and easy problem to find the whole amount of refraction for any given angle of observation; but unfortunately the uniformity of decrease in the density of the atmosphere, which, according to theory, is in geometrical progression, is so much interrupted by the multitude of causes which may tend to produce this effect, that it is found that the quantity of refraction computed on this principle, will by no means agree with that deduced from actual observation. It has been, however, demonstrated, that the quantity of refraction, in all cases exceeding 10 or 12 degrees of elevation, is not sensibly affected by any irregularity in the law of density, in the strata of which we have supposed the atmosphere to be composed, but that it depends simply upon its pressure and temperature at the time and place of observation, which are indicated at the time by the barometer and thermometer. It was formerly thought, also, that refraction was influenced by the degree of humidity and dryness of the air; but from a great variety of interesting and accurate experiments, carried on by M. M. Biot and Arrago, it appears indisputably established, that no sensible effect is thence produced. See a memoir on this subject by the former author, in vol. x. of the National Institute.

But before we proceed farther on this interesting subject, it will be proper to give a sketch of the several improvements which the theory has experienced in the hands of different celebrated astronomers; in doing which we shall avail ourselves of a memoir, published by Dr. T. S. Evans in the Philosophical Magazine, which contains a minute and circumstantial detail of many important particulars connected with this subject. There appears to be but little doubt

that the astronomic refraction was known to the ancients, since it is expressly mentioned by Ptolemy, although not made use of in his calculations. He says, near the end of the 8th book of the *Almagest*, that in the rising and setting of the heavenly bodies, there are changes which depend upon the atmosphere, and he mentions it more at length in a work on optics, which, unfortunately, has not been handed down to us. Alhazen, an Arabian writer, who is generally supposed to have lived about the year 1100, and to have taken the greater part of his optics from the works of Ptolemy, speaks also decidedly of it, and shews the manner of convincing ourselves of it by experiment. "Take," says he, "an armillary, which turns round its poles, and measure the distance of a star from the pole of the world when it passes near the zenith in the meridian, and when it is rising or setting near the horizon, and you will find the distance from the pole less in the latter case." He then demonstrates that this must arise from refraction, but he does not state its quantity.

In the collection of observations made by Bernard Walter, and published by Willebrode Snell in 1618, it is stated, that the observations were so exact, that they pointed out to Walter the quantities by which the altitudes of the stars and planets were increased on account of the refraction.

Tycho Brahe, however, appears to be the first who asserted, with any degree of accuracy, that the refraction elevates the heavenly bodies rather more than half a degree when on the horizon. (See *Progymn.* p. 15.) But either his instruments or his observations were not sufficiently correct to determine it with certainty for all degrees from the zenith to the horizon; and, accordingly, where these failed, the rest were supplied by conjecture. He believed that the sun's refraction was 34' in the horizon, and that it became insensible at 45° of altitude. For the stars, however, he assumed an entirely different quantity, *viz.* 30' in the horizon; but this, according to him, terminated at only 20° of altitude.

The following is the manner in which it is related (*Encly. Method.*) that Tycho made this discovery. He had determined, with one or two instruments extremely well made, the latitude of the place by observations of Polaris above and below the pole. He determined it also by the sun's altitude in both solstices, and found it four minutes less in the latter. At first he doubted the goodness of his instruments, and therefore constructed, with the utmost care, as many as ten others, of different sizes and forms, but they all gave nearly the same results. He could, therefore, no longer attribute this difference in the two determinations of the latitude to any defect in the observations, but endeavoured, by an attentive consideration of the subject, to find out the cause of this singular phenomenon. At length he supposed it could only arise from the refraction which elevated the sun at the winter solstice, having then only 11° of elevation above the horizon. This result agreed very well with the principles of optics; but still Tycho Brahe could scarcely persuade himself that the refraction was sufficiently large to produce so great a difference. On this account, he made other instruments of ten feet diameter, whose axes corresponded exactly with the pole of the world, and with these he measured the declination of the stars out of the meridian. He then found, that even in summer the refraction, although insensible at the meridian altitude of the sun, was very considerable near the horizon, and amounted to half a degree in the horizon. See *Progymn.* p. 79—104. *Street's Astr. Carol.* p. 119.

REFRACTION.

Tycho Brahe's table of refraction is as follows :

Alt.	Refraction.	Alt.	Refraction.
0°	30' 0"	0	1 "
1	21 30	11	5 00
2	15 30	12	4 30
3	12 30	13	4 00
4	11 00	14	3 30
5	10 00	15	3 00
6	9 00	16	2 30
7	8 15	17	2 00
8	6 45	18	1 15
9	6 00	19	0 30
10	5 30	20	0 00

In this state the refraction remained for many years. Even Riccioli, in 1665, supposed it nothing at about 26° of altitude; but he thought the moon had only 29' of horizontal refraction in summer, the sun 30', and the stars 30' 37". It was not till after the year 1672, that a tolerably near table of refraction made its appearance, when the elder Cassini took the subject into consideration. (Mem. de l'Acad. tom. v. p. 81.) What led to this was the voyage of Richer to Cayenne in that year, upon the utility of which some very excellent remarks were made by Cassini, shewing how far observations made in a situation so near the equator tended to confirm or disprove certain theories derived from observations made in Europe. Several very useful deductions were drawn from a comparison of those made both at Paris and Cayenne; among others, the refraction was settled upon more accurate elements than heretofore, and a new table computed, for the first time, of its quantity, for all degrees, up to the zenith; an abridgment of which is given below :

Alt.	Refraction.	Alt.	Refraction.
0°	32' 20"	0	1 "
1	27 56	30	1 42
2	21 04	40	1 10
3	16 06	45	0 59
4	12 48	50	0 50
5	10 32	60	0 34
10	5 28	70	0 21
15	3 36	80	0 10
20	2 39		

From the relation of his grandson it appears, however, that Cassini had at one time computed three tables of refraction for all altitudes; one for winter, another for summer, and a third for spring and autumn; but several doubts having been suggested to him respecting this arrangement, although in appearance conformable to nature, and principally the observations of Richer at Cayenne, where the refraction was found little different from that at Paris, he changed his opinion; and judging, that since the great difference of heat of the torrid zone from that of the temperate zone, which we inhabit, does not cause sensible differences in the refraction; therefore the greatest heat or cold of our climate could not change it much; and he then fixed upon one table, which was that used by the astronomers of the Royal Observatory of Paris up to the year 1745.

It was always thought, before the time of Cassini, that the refraction did not extend its influence higher than 45° of altitude: and he is generally considered as the first who proved that it reached all the way to the zenith. He also supposed that near the equator the horizontal refraction was less than in our climate by about one-third; that this difference decreased as far up as 60°, after which it was the same nearly for both climates.

From this discovery it followed, as a natural consequence, that the refraction must be greater near the pole than at Paris: and this was shortly afterwards proved to the Academy by the publication of a work expressly on that subject. (*Refractio solis in occidentis, &c.* Holmiæ, 4to. 1695.) The king of Sweden, being, in 1694, at Tornea, in West Bothnia, near the latitude of 65° 45', and observing that the sun did not set there in the summer solstice, sent the following year some mathematicians to make more certain and exact observations of this curious phenomenon. They are contained in this book, and Messrs. Cassini and De la Hire concluded from them, that in the latitude of 65° 45' the horizontal refraction must be 58', or nearly double of that at Paris.

According to an observation made by some Dutchmen who passed the winter of 1596—7, in Nova Zembla, in latitude 76° north, the sun, which had entirely disappeared the 14th of November, began to rise again the 24th of January, viz. six days sooner than was expected, according to astronomical calculations. If so, when the sun has been two or three months under the horizon, as the Dutchmen observed in 1597, the cold becomes dreadful, and perhaps the refraction increases prodigiously. M. le Monnier assures us, that he found by the observations printed in 1599, that on the 24th and 27th of January 1597, there were more than 4½ degrees of refraction: that he could neither explain these observations, reject them as doubtful, nor suppose any error, as was done by most of the other astronomers, Kepler, Cassini, Scotø, and, lastly, M. le Gentil, in his *Voy. dans les Mers des Indes*, tom. i. p. 395. tom. ii. p. 832, who maintained that there were errors in the observations, and accordingly read a memoir on the subject. If it were not so difficult a task to winter in these high latitudes, we might expect such observations as would remove all doubt on the subject; and, perhaps, bring others to light of as great or greater importance.

The refraction of the north being so considerable, is very useful to the inhabitants, who are deprived of the sun's light during many months; as it makes the sun rise much earlier, and set much later to them, than it otherwise would.

About the year 1725, Mr. Flamsteed, the English astronomer royal, published his table computed from his own observations: and this was the one commonly used in England for many years afterwards.

Sir Isaac Newton also constructed one from theory, which was first published by Dr. Halley in the *Philosophical Transactions*, N° 368, for 1721. He made the horizontal refraction 33' 45"; whereas Mr. Flamsteed's was only 33' 0".

But although the refraction might be determined within a few seconds at all altitudes by observation; yet, the law of its increase from the zenith to the horizon was a subject that occupied the principal mathematicians and astronomers for more than a century. Newton having discovered the general principles of attraction, found that the refraction was a consequence of this law of nature; and that it arose from the attraction of the atmosphere on the particles of light. On this principle the curve which a ray of light describes might be determined: since it is successively attracted

REFRACTION.

tracted by different layers of the atmosphere, increasing in density as they approach the earth, and, consequently, bending the ray more and more from the right line which it described in the vacuum previous to its reaching the atmosphere. There are many authors who have endeavoured to find from theory the curve described by this ray in its course, by the assumption of various hypotheses; but perfection, and our attempts to arrive at it, as is well observed by the elder Cassini in discoursing on this subject, are like the progress of certain curves and their asymptotes. The principal of these writers on the subject are Bernoulli (*Hydrodyn.* 1738, p. 221.); Boscovich (*Oper.* tom. ii.); Bouguer (*Prix de 1729. Memoires*, 1739, p. 407; 1749, p. 75.); Cassini (*Epit. ad Montanari*, 1665. *Refractioni e Parallole, &c.* 1671. *Mem. for 1714*, and his *Astr.* vol. i. p. 11. Paris, 1740, in 2 vols. 4to.); Descartes (*Dioptrique*, 4to. Paris, 1637); De la Grange (*Nouveaux Mémoires de Berlin*, vol. iii.); Euler (*Mem. de Berlin*, 1754, tom. x.); Gregory (*Astronomy*, vol. i. p. 358. edit. of 1715, in 8vo.); Hodgson (*Mathematics*, vol. i. p. 367. *Fluxions*, p. 133.); Huygens (*Traité de la Lumiere*, p. 44. *Dioptrica*, 4to. 1703); Kramp (*Analyse des Refract. Astr. et Terres*, 4to. Straßburg, 1799); Lambert (*Les Propriétés Remarquables de la Route de la Lumiere. A la Haye*, 1759. Another edition in German, 1773); La Place (*Mécanique Céleste*, vol. iv. p. 231.); Mayer (*Tables*, 1770); Newton (*Principia*, b. i. sect. 14.); Oriani (*Ephem. de Milan*. 1788); Thomas Simpson (*Mathematical Dissertations*, 1743); Brook Taylor (*Methodus Incrementorum*, 4to. Lond. 1715. *Propof.* 27. p. 108.); Heinius (*Dissertatio de Computo refractionum Astron.* 4to. Leipzig, 1749); Tobias Mayer (*De Refractionibus Astronomicis*, 4to. Altorf. 1781); La Hire (*Mem. de l'Acad. pour 1702*, p. 52.); d'Alembert (*Opuscules Mathématiques*, tom. viii. p. 297.)

It was conjectured by many of the early writers, that the refraction was subject to variations depending upon the weather: but it then amounted to little more than a conjecture, on account of the indifferent manner in which astronomical instruments were divided. Picard found by meridian altitudes of the sun in 1669, that it was greater in winter than in summer. He found also that it was less by day than by night. In the observations given at the end of his journey to Uraniburg, to settle the latitude of that place, and its difference of longitude from Paris, for the purpose of comparing the observations of Tycho Brahe with those made at the Royal Observatory of Paris, he found the horizontal refraction for the first limb of the sun that made its appearance above the horizon there 33' 2", and for the second 32' 37". So that in the small interval of time that the sun was in rising, the refraction was diminished 25 seconds by the warmth arising from the sun's presence.

A quadrant being also directed by him from the top of Mount Valerian towards the summit of the church of Notre Dame at Paris, he found the depression 20'; but the sun had scarcely risen, when it was increased to 22'; exhalations being raised by the sun's presence, and the medium between Paris and Mount Valerian become more equal; whereas, before the sun rose, the air of Paris was more dense than that of Mount Valerian.

The density of the atmosphere being the immediate cause of the refraction, it was very natural to suppose that it must decrease as this density became less; whether by causes which diminished its weight, or by the expansion produced by heat: and, indeed, astronomers were not long after this, before they discovered that very sensible differences were occasioned by these circumstances.

But all the honour of introducing corrections on account

of the variation of density in the atmosphere, as indicated by the barometer and thermometer, is due to Messrs. Lowthorpe and Hauksbee; the former of whom, in 1698, proved by a very simple experiment, in the presence of the Royal Society, that the refractive power of air is directly proportional to its density: and the latter, by repeating and extending the same course of experiments in the year 1708, with the machinery pointed out by the former, found that the variations of refraction, depending on the barometer, are proportional to the alteration of height of the mercury in the tube: and by a series of these experiments, he furnished us with a table of the corrections which it is necessary to make on account of the changes of heat indicated by the thermometer. These experiments, although not quite conclusive on the subject, were yet made with as much accuracy and care as the nature of the machinery, and the state of experimental philosophy of that time, would admit. An example is also given, towards the end of his paper, on the mode of applying them to correct the refraction. By these, Hauksbee found that a volume of air expressed by unity, when the thermometer was at 180° above zero, became, at 50° below, one-eighth more dense: or, which is the same thing, that the air lost one-eighth of its density, for an elevation of 180° of Fahrenheit's thermometer; which is exactly the difference of heat between melting ice and boiling water. But although this one-eighth, as will be shewn hereafter, was too small; yet it laid the foundation for other experiments, since made by several philosophers, by which the quantity of expansion has been determined more accurately.

We have already shewn that the refraction near the pole is greater than in our climate; the degree of cold being more intense. It was also found to be less in the torrid zone, where the heat is greater than in Europe. Bouguer made a variety of observations at Peru, the result of which he has given us. In 1740, he came down into an island situated in the river of Emeralds, called Isle of Inca, where he determined the refraction from 1° to 7° of altitude; and the table which he afterwards computed shews the refraction to be about one-seventh less than in Europe. The horizontal refraction he found to be 27': but at 6° of altitude it is 7' 4"; and at 45°, it is 44". Bouguer then gives a table for Quito, which is more elevated above the level of the sea. M. le Gentil found it greater at Pondicherry in India, although in the torrid zone.

The refraction diminishes when we are elevated above the level of the sea. Bouguer observed the quantity of it at Chimborazo, 2388 toises above the level of the sea, and found it in the horizon only 19 $\frac{3}{4}$ '. At the cross of Pitchea, 2044 toises above the sea, he found it 20' 48"; at Quito, 1479 toises above the sea, 22' 50": but at the level of the sea 27'. These observations, when joined with the theory, produced the following rule; *viz.* if we take the excess of 5158 toises above the elevation of the place, with regard to the level of the sea, the refraction will be as the square root of this excess. Thus the square root of 5158 toises is 27', for the horizontal refraction, at the level of the sea, in the torrid zone: and the square root of the excess of 5158 above the elevation of the place will be its horizontal refraction. The quantity 5158 is the height above which the refractive matter no longer produces any sensible effect, at least in the torrid zone.

But although by this time considerable attention had been paid to the subject, yet great differences were to be found in the tables then most in use. Thus at the altitude of 30°, according to Flamsteed, the refraction was 1' 23"; Newton, 1' 30"; Cassini, 1' 42"; and de la Hire, 1' 55"; leaving an uncertainty of more than half a minute: and it must have been very mortifying to an observer, after having taken the

utmost

REFRACTION.

utmost pains to avoid errors of two or three seconds; to find his reduced observations liable to so great an error, according to the choice of his table of refraction.

It is indeed rather extraordinary, that in a memoir published by Cassini de Thury, among those of the Academy for 1745, he attempted to reconcile a number of observations with each other, by considering the state of the thermometer only, without at all noticing that of the barometer; although at that time Haukbee's experiments had been published about 37 years.

He concludes his paper, as is very natural to suppose, without being able to make the observations agree; nor does it clearly appear that the French noticed the above-mentioned experiments made by Haukbee till about the year 1749. It is also worthy of remark, that although the necessity of introducing corrections on account of the alterations of the barometer and thermometer were likewise shewn to be absolutely necessary by Dr. Halley (Phil. Trans. N^o 364), and the circumstance mentioned, and in some degree admitted by Le Monnier (Hist. Celest.), yet it does not appear that he followed the advice of his illustrious contemporary, but merely endeavoured, as Cassini did, to reconcile his observations with the state of the thermometer at the time of making these observations, without taking the barometer into account.

It would be endless to notice the different opinions respecting both the terrestrial and the astronomic refraction which are to be met with in the writings of various authors on the subject: and it would be equally useless to notice all the tables of its quantity given by them, some of which differ very much from others. It will be sufficient to mention those only who made some considerable advances towards obtaining it with greater accuracy.

The next of these in order was La Caille (Mem. de l'Ac. de Sc. 1755, p. 547.), who in determining it certainly bestowed very great pains, by making and reducing an immense number of observations, and afterwards comparing them with others made at Greenwich by Dr. Bradley, at Gottingen by Mayer, at Bologna by Zanotti, and by La Lande, who was then at Berlin. From these it appeared that the refraction at 45° of altitude was 1' 6½" but this, as will hereafter be seen, was too great by some seconds. In his paper on the subject, which is divided into four parts, he proves, first, that the mean refractions are very nearly the same for the same apparent altitudes throughout the whole extent of the temperate zone; since those which were observed at Paris did not exceed those observed at the Cape of Good Hope but by ¼" at most. In the second he determines the absolute quantity of the mean refraction for the apparent height of the pole at Paris, and gives the result of his observations with regard to the latitude of Paris and of the Cape of Good Hope. In the third he gives his table of mean refraction, and another of corrections depending upon the state of the barometer and thermometer; concluding with some reflections on its construction and use. In the fourth he compares his new table with the most celebrated of those that had before that time been in use among astronomers; and he then shews how it agrees with the observations of Bradley, Zanotti, and Mayer.

But by La Caille's memoir it appears, that previous to this time M. Mayer had formed and communicated to him a table of astronomic refractions which he computed by means of an algebraic formula, the co-efficients of which he deduced from his own observations, and took into account the variations relative to those of the barometer and thermometer. He found the alteration of refraction for a depression of 15 lines in the barometer, the same as for a rise of 10" in the thermometer, and the variation for each degree of

the latter, according to his table, ¼" of the whole mean refraction, which he adapted for 28 inches of the barometer, and 0° of the thermometer. This proportion takes place down to 80° of zenith distance. Mayer considered also that the mean refraction is the same for all parts of the earth; and that the only variation which takes place depends on the changes of the weight and temperature of the atmosphere.

La Caille, in comparing Mayer's table with observations, found that his correction for the thermometer was a little over-rated; and accordingly, for his new table, altered it to ⅓" for each degree. And here it may be observed that La Caille did not correct his altitudes above 36° at Paris, and 30° at the Cape; first, because he only noted the barometer and thermometer in the night, when he observed stars below 30° of altitude. Secondly, because, that at 36° of altitude, where the mean refraction is about 1½ minute, the variation which belongs to 10° of the thermometer only amounts to 3½ seconds; a quantity about equal to the limits of the errors of observations made with an instrument of six feet.

The formula given by Euler (Mem. de l'Ac. de Berlin, 1754, p. 131.), appeared also about this time. It took into account the variation of the refraction depending upon the thermometer and barometer, but was certainly too complicated to be generally adopted. He shews, however, that in very different hypotheses the refraction will be sufficiently exact, if taken in the inverse ratio of the degrees of heat, when the star or planet is not too near the horizon, but the precise quantity of this ratio was unknown to him.

In this state the refraction stood when Dr. Bradley took the subject into consideration, and began to find its quantity from his own observations. The rule which he adopted, although a very elegant one, he neither lived to complete nor to present to the world; but it was published after his death by Dr. Maskelyne, (Pref. to 1st vol. of Obs. 1765, Phil. Trans. 1764 and 1787, p. 157. Req. Tables, &c.), and has commonly been used in England up to the present time. He found the mean refraction at 45° of altitude 57", and, that at all other altitudes, it was equal to 57" multiplied by the tangent of the zenith distance, diminished by three times the refraction. Then supposing the mean state of the atmosphere to be at 29.6 inches of the barometer, and 50° of Fahrenheit's thermometer, he made the true or corrected refraction equal to 57" × *t*, (Z. D. - 3*r*)

$$\times \frac{\text{barom.}}{29.6} \times \frac{400}{350 + \text{ther.}}$$

where it is to be understood

that the mass of air is supposed to increase in bulk ⅓" for each degree of Fahrenheit's scale.

A variety of experiments has been made at various times to ascertain the increase in bulk of a quantity of air represented by unity for a certain number of degrees of rise of the thermometer. The following is a list of some of them;

	for 1°
M. Bonne	1.00 25777
Bradley	1.00 25000
Dalton	1.00 20701
De Luc	1.00 20888
Fahrenheit	1.00 25777
Gay Lussac	1.00 20868
Groombridge	1.00 21000
Haukbee	1.00 06933
La Caille	1.00 22222
Mayer	1.00 20444
Shuckburg	1.00 22222
Mean of all except Haukbee's	1.00 22490

REFRACTION.

The refraction deduced from Bradley's very neat and simple formula was, in a few years, adopted by nearly all the astronomers of eminence throughout Europe. The extreme facility with which it might be computed, and the corrections applied, whether from the formula itself, or from tables ready calculated for that purpose, was a powerful recommendation in its favour; but its near agreement with observation soon established it.

We must now, without entering farther into detail of minor improvements, proceed at once to the chapter given by La Place on this subject, in his "Mecanique Celeste," vol. iv. p. 231, where he has drawn, from an investigation which we cannot undertake to exhibit in this place, the following general formula, for expressing the refraction for all angles of elevation above 12 decimal, or 10.8 sexagesimal degrees, viz.

$$r = \frac{a p \cdot \tan. z}{0.76(1+t.0.00375)} - \frac{a p}{0.76} \cdot 0.00125254 \frac{\tan. z}{\text{cof.}^2 z} + \frac{\frac{1}{2} a^2 \text{fin. } 1'' p^2}{[0.76(1+t.0.00375)]^2} \times \frac{(1+2 \text{cof.}^2 z) \tan. z}{\text{cof.}^2 z};$$

where all the quantities are known except r and a ; which latter represents a constant co-efficient; viz. z is the observed zenith distance under the barometric pressure p , in metres, and t the temperature of the centigrade thermometer, r being the refraction: all, therefore, that is required for determining r , is the value of the unknown co-efficient a ; which is to be drawn from observations on the circumpolar stars, in the following manner.

Let Z be the distance of one of these stars from the zenith, in its superior meridian passage; Z' , this distance at the inferior meridian passage, observed from the same point of the terrestrial surface; r and r' , the corresponding refractions. Now all the other quantities, except a , being known, we may, for the sake of simplicity, put the above formula for both passages under this form,

$$r = Aa + B a^2, \quad r' = A' a + B' a^2;$$

where A, B, A', B' , are all known quantities. Writing also Z, Z' , for the observed zenith distances, the true zenith distance, D , corrected for refraction, will be

$$Z + Aa + B a^2, \quad \text{and} \quad Z' + A' a + B' a^2,$$

which are, therefore, now equal to each other; consequently, by addition, we have

$$Z + Z' + (A + A') a + (B + B') a^2 = 2D;$$

in which all the quantities are known, except a and D . But by repeating similar observations on some other star, and denoting by $Z'', Z''', A'', A''', B'', B'''$, the similar quantities before represented by $Z, Z', A, A', \&c.$ also a and D remaining the same for all stars observed in the same place, we shall have these two equations:

$$Z + Z' + (A + A') a + (B + B') a^2 = 2D, \\ Z'' + Z''' + (A'' + A''') a + (B'' + B''') a^2 = 2D;$$

from which it is obvious, the constant co-efficient a may be obtained by the usual methods of elimination.

In the above operation, however, we have supposed the polar distances of the same star to be the same for its superior and inferior passage; whereas we know that, in consequence of the effect of precession, nutation, and aberration, this distance is constantly varying; and we ought, therefore, to introduce these variations into the above equation. But our object being merely to give a general view of the principles made use of for the determination of the

co-efficient a , we have not thought it necessary to enter so strictly into the minutia of the computation. It appears from the above, that the constant co-efficient a may be determined by means of four observations on two different circumpolar stars; and consequently, that every such set of observations ought to produce the same result, or the same value of a . Considering, however, the extreme accuracy required in such cases, both in the instruments and the application of them, some little disagreement is to be expected; and indeed one is surprised to see it so small, as it has been found to be in various observations undertaken for this purpose, and the mean of which we have every reason to consider as perfectly correct; and which is stated by M. Biot, who has interested himself very much on this subject, at $187''.24$ for the decimal division, or $60''.666$ for the sexagesimal.

But now, in order to simplify our first formula, by taking $p = 0.76$ metres, and $t = 0$, this may be put under the form,

$$r = a \tan. Z \left(1 - \frac{0.00125254}{\text{cof.}^2 z}\right) + \frac{1}{2} a^2 \text{fin. } 1'' \frac{1 + 2 \text{cof.}^2 z}{\text{cof.}^2 z} \tan. Z;$$

in which, substituting for $\text{cof.}^2 z$, its value $\frac{1}{1 + \tan. z^2}$, and the proper numerical value of a , as above found, as also of $\text{fin. } 1''$, the whole is reduced to the following form, viz.

$$r = 0.99918761 \cdot a \tan. Z - 0.001105823 \cdot a \tan. z^3 Z;$$

which latter form M. Biot has shewn to be equivalent to

$$r = 187''.24 \cdot \tan. (Z - 3.25 r) \text{ for the decimal division;} \\ r = 60''.666 \cdot \tan. (Z - 3.25 r) \text{ for the sexagesimal division.}$$

But the reduction of it to this form would occupy more space than can be allowed for this article. This last form is as simple as can be desired, from which the following rule in words may be deduced, viz. *The refraction under the same barometric pressure, and the same degree of temperature, is proportional to the tangent of the apparent zenith distance of the star, diminished by $3\frac{1}{4}$ times the refraction.*

It must be remarked, however, that the formula $r = A \tan. (Z - 3.25 r)$, though it exhibits the law of refraction in as simple a form as can be desired, is not well adapted for calculation, in consequence of r entering on both sides of the equation; and astronomers have, therefore, given different methods of rendering the above formula more commodious. In order to which, it is first put under the form,

$$\tan. nr = \tan. z n R \tan. (Z - nr);$$

R representing the refraction, answering to $Z = 90^\circ$. Let us now add successively to both sides of this equation, the quantities $+\tan. nr \tan. z n R - \tan. nr \tan. z n R$, and we shall have,

$$\tan. nr (1 + \tan. z n R) = \tan. z n R [\tan. (Z - nr) + \tan. nr], \\ \tan. nr (1 - \tan. z n R) = \tan. z n R [\tan. (Z - nr) - \tan. nr].$$

Now, dividing these equations, member by member, nr will be eliminated, and we obtain

$$\frac{1 + \tan. z n R}{1 - \tan. z n R} = \frac{\tan. (Z - nr) + \tan. nr}{\tan. (Z - nr) - \tan. nr},$$

$$\text{or } \frac{1}{\text{cof. } z n R} = \frac{\text{fin. } Z}{\text{fin. } (Z - z n R)};$$

whence we draw

$$\text{fin. } (Z - z n R) = \text{cof. } z n R \cdot \text{fin. } Z.$$

REFRACTION.

Now Z and nR being known, we may compute the second side of this equation; whence the arc $Z - 2nr$ is known, and consequently $2nr$; which, divided by $2n$, will give r , as required. But it may be found still more simply by the formula,

$$\tan. nr = \tan. nR \tan. \frac{1}{2} n;$$

$\tan. n$ being found by means of the auxiliary equation,

$$\tan. u = \sin.^2 nR \cdot \tan. Z.$$

On the principle above explained, the following table of refractions has been computed, agreeing with the temperature of $+14^\circ$ on the centigrade thermometer, and under a pressure of 0.76 metres of the barometer; which is the same as $57^\circ.2$ Fahrenheit, and 29.922 English inches. And for any other temperature and pressure, the corresponding corrections must be made as indicated in Tables II. and III.; which tables are computed by means of the general formula given in the preceding part of this article.

We had intended to give here a short abstract of a very interesting paper on this subject, published by Mr. Groombridge, in the Philosophical Transactions for 1810; but having already exceeded our usual limits, we can only refer the reader to the volume itself, where he will find several neat and useful formulæ.

Having thus given a sketch of the method of determining the quantity of astronomical refraction for all angles of elevation, and under various degrees of temperature and barometric pressure, let us add a few words on the subject of terrestrial or horizontal refraction; for the determination of which, the following method has been successfully practised in the English Trigonometrical Survey.

Let A, A' , (*Plate XIX. Astronomy, fig. 11.*) be two elevated places on the surface of the earth; BD , the intercepted arc of the earth's surface; C , the centre of the earth; $AH', A'H$, the horizontal lines at A, A' , produced to meet the opposite vertical lines CH', CH . Let a, a' , represent the apparent places of the objects A, A' ; then is $a'A A'$ the refraction observed at A , and $aA' A$ the refraction observed at A' ; and half the sum of these angles will be the horizontal refraction, if we assume it equal at each station.

Now an instrument being placed at each of these stations A, A' , the reciprocal observations are made at the same instant of time, which is determined by means of signals or watches previously regulated for that purpose; that is, the observer at A takes the apparent depression of A' , at the

same moment that the other observer takes the apparent depression of A . Then, in the quadrilateral $ACAI$, the two angles A, A' , are right angles, and consequently the angles I and C are together equal to two right angles; but the three angles of the triangle IAA' , are together equal to two right angles; and consequently the angles A and A' are together equal to the angle C , which is measured by the arc BD . If, therefore, the sum of the two depressions $HA'A, H'A A$, be taken from the sum of the angles $HA'A$, and $H'A A$, or, which is equivalent, from the angle C , (which is known, because its measure BD is known,) the remainder is the sum of the two refractions. Hence this rule, "take the sum of the two depressions from the measure of the intercepted terrestrial arc, half the remainder is the refraction." If, by reason of the minuteness of the contained arc BD , one of the objects, instead of being depressed below the tangent AH' , appears elevated, as suppose A to a'' , then the sum of the angles $a''A A'$, and $aA' A$, will be greater than the sum $IAA' + IA'A$, or than C , by the angle of elevation $a''A A'$; but if from the former sum there be taken the depression $HA'A$, there will remain the sum of the two refractions, so that in this case the rule becomes as follows: "Take the depression from the sum of the contained arc and elevation, and half the remainder is the refraction."

The quantity of this terrestrial refraction is estimated by Dr. Maskelyne at one-tenth of the distance of the object observed, expressed in degrees of a great circle. Whence, if the distance be 10,000 fathoms, its 10th part, 1000 fathoms, is the 60th part of a degree, or one minute, which, therefore, is the refraction in altitude of the object at that distance. But Le Gendre is induced, by several experiments, to allow only one-fourteenth part of the distance for the refraction in the altitude, so that on the distance of 10,000 fathoms, the 14th part of which is 714 fathoms, he allows only $44''$ of terrestrial refraction, so many being contained in 714 fathoms. (See his Memoir on the Trigonometrical Operations.) Again, Delambre makes the quantity of terrestrial refraction to be one-eleventh part of the arc of distance. And the English measurers, from many very exact observations, determine the quantity of the medium refraction to be a twelfth part of the said distance. The mean of all these is about .085 of the intercepted arc, which is probably not very far from the truth: this quantity, however, it must be observed, is found to vary very considerably with the different states of the weather and atmosphere, from one-seventh to one-eighteenth of the contained arc.

REFRACTION.

TABLE II. Of Corrections to the preceding Table of Refractions for different Degrees of Temperature. An Increase of Cold augments Refraction; therefore, the Correction is Additive for a Temperature less than 14° of the Centigrade, and Subtractive for those above it.

To observe the Refraction of a Star, &c. 1. Observe the meridian altitude of a star near the zenith; whence the latitude of the place being known, the true declination of the star is easily had, the star being now void of any sensible refraction. 2. Observe the altitude of the same star in any other degree, and note the time by a pendulum. 3. For the given time of observation, from the declination of the star compute its true altitude.

This being thus found less than the altitude observed, subtract the one from the other; and the remainder is the refraction for that moment, in that degree.

REFRACTION of *Altitude*, is an arc of a vertical circle, by which the altitude of a star is increased by the refraction.

REFRACTION of *Declination*, is an arc of a circle of declination, by which the declination of a star is increased or diminished by the refraction.

REFRACTION of *Ascension and Descension*, is an arc of the equator, by which the ascension and descension of a star, whether right or oblique, is increased or diminished by means of the refraction.

REFRACTION of *Longitude*, is an arc of the ecliptic, by which the longitude of a star is increased or diminished by means of the refraction.

REFRACTION of *Latitude*, is an arc of a circle of latitude, by which the latitude of a star is increased or diminished by means of refraction.

REFRACTION, in *Commerce*, is a term sometimes used by merchants, where there has been an oversight in an account, to the prejudice of a person; who thereupon demands restitution of so much, added or omitted by mistake.

You must make me a refraction of five pounds forgot in your account. I will deduct or make you a refraction of 30s. charged inadvertently in my bill.

REFRACTORY, in *Chemistry*. See an explication of the term under *APYROUS*.

REFRAIN, Fr., in *Music*, the termination of every verse or stanza of a song, by the same words and the same melody. (See *BURDEN*.) The word, according to Menage (*Dict. Etym.*) is derived from the Spanish *refran*.

REFRAN, Span., a proverb; the burden of a song in that language, being usually sententious, and including some moral precept.

REFRANGIBLE, whatever is capable of being refracted. See *REFRANGIBILITY*.

REFRANGIBILITY of *Light*, the disposition of the rays to be refracted.

A greater or less refrangibility is a disposition to be more or less refracted, in passing at equal angles of incidence, into the same medium.

That the rays of light are differently refrangible, is the foundation of sir Isaac Newton's whole theory of light and colours. The truth of the principle, which was investigated and established by our great philosopher in the year 1616, will appear from the following experiments.

1. Let *EG* (*Plate XIX. Optics, fig. 1.*) represent the window-shutter of a dark room, and *F* a hole in it, through which the light is transmitted to the prism *ABC*, which refracts it towards *PT*, where it appears in an oblong form; its length being about five times greater than its breadth, and exhibiting the various colours of the rainbow. In *fig. 2.* *agb* represents a second prism, which refracts the light back again to *Q*, where the image is round; whereas, without the interposition of this second prism, the light would have proceeded to *PT*, and, consequently, have been oblong, as before. In this experiment sir Isaac Newton took care that the plane *ag* was placed exactly parallel to *BC*, and also *bg* to *AC*, that the rays might be equally refracted,

though in contrary ways, by both prisms. He also observed, that both prisms must be placed very near to one another; for if their distance be so great, that colours begin to appear in the light, before its incidence on the second prism, those colours will not be destroyed by the refraction of that prism.

2. Having placed one of two boards behind the prism at the window, so that the light might pass through a small hole made in it for the purpose, and fall on the other board at the distance of about twelve feet, a hole being made in it to admit the passage of the incident light, he then placed another prism behind the second board, so that the light which was transmitted through both the boards might pass through that also, and be again refracted before it arrived at the wall. This being done, he took the first prism in his hand, and turned it about its axis so much, as to make the several parts of the image, cast on the second board, successively to pass through the hole in it, that he might observe to what places on the wall the second prism would refract them; and he saw, by the change of those places, that the light tending to that end of the image, towards which the refraction of the first prism was made, did, in the second prism, suffer a refraction considerably greater than the light which tended to the other end. The true cause, therefore, of the length of that image was discovered to be no other, than that light is not similar or homogeneal, but that it consists of rays, some of which are more refrangible than others; so that without any difference in their incidence on the same medium, some of them shall be more refracted than others; and therefore, that according to their particular degrees of refrangibility, they will be transmitted through the prism to different parts of the opposite wall.

To make this capital experiment, which sir Isaac Newton himself justly calls the *experimentum crucis*, let *SF* (*fig. 3.*) represent a ray of the sun, which, after passing through a hole in the window-shutter *F*, is received by the prism in *ABC*, close behind which is placed a board *DE*, with a hole in it at *G*, to admit any of the rays after they have been separated by the prism; then *de* will represent the other board, placed at a considerable distance from the former, with a hole in it, *g*, to receive any part of the light transmitted through the other board. Behind this second board is placed another prism, *abc*, through which different rays of light, falling upon it in the very same place, and with precisely the same angle of incidence, will be refracted higher or lower, on the opposite wall *MN*. This experiment was conducted with the utmost circumspection and accuracy; and it is observed, that neither the different magnitude of the hole in the window-shutter, nor the different thicknesses of the prism, at the place where the rays passed through it, nor the different inclinations of the prism to the horizon, nor the different matter of the prisms, made any sensible change in the length of the image.

3. In order farther to establish this famous hypothesis of the different refrangibility of the rays of light, he held a prism in a beam of the sun, which was transmitted into the room through a hole in the window-shutter, so that its axis might be perpendicular to that beam; and having turned the prism about its axis to make the image ascend and descend, and when it seemed to be stationary between these contrary motions, he fixed the prism so that the refractions of both sides might be equal to each other. In this situation he looked at the hole through the prism, and observed the length of its refracted image to be many times greater than its breadth: the most refracted part of it was violet, the least refracted red, the middle parts blue, green, and yellow, in order. The same thing happened when he removed the prism

out of the sun's light, and looked through it upon the hole shining by the light of the clouds beyond it.

4. Considering that if the image of the sun should be drawn into an oblong form, either by a dilatation of every ray, or by any other casual inequality of the refractions, the same oblong image would, by a second refraction, made sideways, be drawn out as much in breadth, he placed a second prism immediately after the first, in an oblique position with respect to it, that it might again refract the light of the beam of the sun's light, which came to it through the first prism; so that in the first prism, the beam would be refracted upwards, and in the second sideways. But he found that the breadth of the image was not increased by the refraction of the second prism, but only its upper part, which in the first prism suffered the greatest refraction, and appeared violet and blue, did again, in the second prism, suffer a greater refraction, than the lower part of it, which was red and yellow, and this without any dilatation of the breadth of the image. Thus let *S* (*fig. 4.*) represent the sun, *F* the hole in the window, *ABC* the first prism, and *DH* the second. If *Y* represent the round image of the sun, made by a direct beam of light, when the prisms are taken away, *PT* will be the oblong image of the sun, made by the same beam passing through the first prism only, and *pt* will be the image made by the cross refractions of both prisms together. Sometimes he placed a third prism after the second, and sometimes a fourth after the third; by all which the image might be often refracted sideways, but the rays which were more refracted than the rest in the first prism, were also more refracted in all the others, and that without any dilatation of the image sideways; and, therefore, those rays, on account of their constancy of a greater refraction, he called the more refrangible ones. He observes, in order to render the meaning of this experiment more evident, that all the rays, which are equally refrangible, fall upon a circle answering to the sun's disc. Let, therefore, *AG* (*fig. 5.*) represent the circle which all the most refrangible rays, transmitted from the whole disc of the sun, would illuminate, and paint upon the opposite wall, if they were alone. Let *EL* be the circle which all the least refrangible rays would, in like manner, illuminate, and paint, if they were alone, and let *BH*, *CJ*, and *DK*, be the circles which so many intermediate kinds of rays would successively paint upon the wall, if they were singly propagated from the sun, the rest being always intercepted, and conceive that there are other intermediate circles without number, which other innumerable intermediate kinds of rays would successively paint upon the wall, if the sun should successively emit every kind by itself. Now since the sun emits rays of all these kinds at once, they must altogether illuminate and paint innumerable equal circles, of all which, being ranged according to their different degrees of refrangibility, the oblong image *PT* before described is composed.

Now if the sun's circular image, *Y*, which is made by an unrefracted beam of light, was by any dilatation of the single rays, or by any other irregularity in the refraction of the first prism, converted into the oblong image *PT*, then ought every circle in the image to be in like manner drawn out into a similar oblong figure, contrary to the result of this experiment.

He considered farther, that by the breadth of the hole through which the light enters into the dark chamber, there is a penumbra made in the circumference of the image *Y*, which is also visible at the sides of the oblong images *PT* and *pt*. He, therefore, placed at that hole a lens, or object-glass of a telescope, which might cast the image of the sun distinctly on *Y*, without any penumbra at all; and he

found that the penumbra of the rectilinear sides of the oblong images *PT* and *pt* was also thereby taken away, so that they were as distinctly defined as the circumference of the first image *Y*.

There are some other circumstances attending this experiment, by which the conclusion drawn from it is made still more plain and convincing.

Let the second prism, *DH*, (*fig. 6.*) be placed not immediately after the first, but at some distance from it, so that the light from the first prism may fall upon it in the form of an oblong spectrum *qr*, parallel to this second prism, and may be refracted sideways, to form the oblong image, *pt*, upon the wall, and it will be found that this image, *pt*, is inclined to the image *PT*, which the first prism would have formed without the second; the blue ends, *P* and *p*, being farther distant from one another than the red ones, *T* and *t*; and, consequently, the rays which go to the blue end, *q*, of the image *qr*, and which, therefore, suffer the greatest refraction in the first prism, are again, in the second prism, more refracted than the rest.

At two holes made near one another in his window-shutter, he placed two prisms, one at each, which might cast upon the opposite wall two oblong coloured images of the sun; and at a little distance from the wall he placed a long slender paper, with straight and parallel edges; and he placed the prisms and papers, so that the red colour of one image, at *T*, (*fig. 7.*) might fall directly upon one half of the paper, and the violet colour, *M*, of the other image, upon the other half of the same paper. Then with a black cloth he covered the wall behind the paper, that no light might be reflected from it to disturb the experiment; and viewing the paper through a third prism, held parallel to it, he saw that half of it which was illuminated by the violet light to be divided from the other half, by a greater refraction, especially when he retired to a considerable distance from the paper.

He farther caused the two images, *PT* and *MN* (*fig. 8.*) to coincide, in an inverted order of their colours, the red end of each falling on the violet end of the other; and then viewing them through a prism *DH*, held parallel to their length, they no longer appeared coincident, as when they were viewed with the naked eye, but in the form of two distinct images, *pt* and *mn*, crossing one another in the middle; which shews that the red of the one image, and the violet of the other, which were coincident at *PN* and *MT*, being parted from one another by a greater refraction of the violet to *pm*, than that of the red to *n* and *t*, differ in degree of refrangibility.

Having placed a prism, whose two angles at its base were equal to one another, and half right ones, and the third a right one, in a beam of the sun's light, admitted into the room as before, he turned it slowly about its axis, till all the light which went through one of its angles, and was refracted by it, began to be reflected by its base, (at which, till then, it went out of the glass,) and then he observed that those rays which had suffered the greatest refraction were sooner reflected than the rest. He imagined, therefore, that those rays of the reflected light, which were most refrangible, did first of all, by a total reflection, become more copious in that light than the rest; and that afterwards the rest, also, by a total reflection, became as copious as these. To try this, he made the reflected light pass through another prism, and, being refracted by it, to fall afterwards upon a sheet of white paper, at some distance behind it, and there to paint the usual colours of the prism. Then causing the first prism to be turned about its axis, he observed, that when those rays which, in this prism, had suffered the

greatest

REFRANGIBILITY.

greatest refraction, and were of a blue and violet colour, began to be wholly reflected, the blue and violet light on the paper, which received the rays from the second prism, was sensibly increased, above that of the red and yellow, which was least refracted; and afterwards, when the rest of the light, which was green, yellow, and red, began to be wholly reflected in the first prism, the light of those colours on the paper received as great an increase as the violet and blue had done before. From this it is manifest, that the beam reflected by the base of the prism, being augmented first by the more refrangible rays, and afterwards by the less refrangible ones, is compounded of rays differently refrangible. This experiment is illustrated by *fig. 9*, in which *A B C* represents the first prism, on the base of which the light falls, at *M*. When this prism is turned about its axis, according to the order of the letters *A B C*, the more refrangible rays, *M H*, emerge more and more obliquely; and at length, after their most oblique emergence, are reflected towards *N*, and going on to *p*, increase the number of rays *N p*. By continuing the motion of the first prism, the less refrangible rays, *M G*, are reflected to *N*, and increase the number of rays *N z*.

Since it appears from sir Isaac Newton's experiments, that different rays of light have different degrees of refrangibility, it necessarily follows that the rules laid down by preceding philosophers, concerning the refractive power of water, glass, &c. must be limited to the middle kind of rays, as it may be supposed that Kepler, Snellius, and others would attend to them principally. Sir Isaac, however, proves that the sine of the incidence of every kind of light, considered apart, is to its sine of refraction in a given ratio. This he deduces both by experiment, and also geometrically, from the supposition that bodies refract the light by acting upon its rays in lines perpendicular to their surfaces.

Upon the whole it appears, that the blue rays are more refracted than the red ones, and that there is, likewise, unequal refraction in the intermediate rays; and upon the whole it appears, that the sun's rays have not all the same refrangibility, and, consequently, are not of the same nature. It is also observed, that those rays which are most refrangible are also most reflexible. See the proof of this under REFLEXIBILITY. Newton's Optics, p. 22, &c. ed. 3.

The difference between refrangibility and reflexivity was first discovered by sir Isaac Newton, in 1671-2, and communicated in a letter to the Royal Society, dated February 6, 1671-2, and published in the Philosophical Transactions, N^o 80, p. 3075, and from that time vindicated by him from the objections of several authors; particularly F. Pardies, M. Mariotte, Fr. Linus, or Lin, and other gentlemen at the English college at Liege; and at length it was more fully laid down, illustrated, and confirmed, by a great variety of experiments, in his excellent treatise of Optics.

But farther, as not only those colours of light produced by refraction in a prism, but also those reflected from opaque bodies, have their different degrees of refrangibility and reflexivity; and as a white light arises from a mixture of the several coloured rays, the same great author concluded all homogeneous light to have its proper colour, corresponding to its degree of refrangibility, and not capable of being changed by any reflections, or any refractions; that the sun's light is composed of all the primary colours; and that all compound colours arise from a mixture of the primary ones, &c.

The different degrees of refrangibility he conjectures to

arise from the different magnitude of the particles of which the different rays consist. Thus the most refrangible rays, *i. e.* the red ones, he supposes to consist of the largest particles; the least refrangible, *i. e.* the violet rays, of the smallest particles; and the intermediate rays, yellow, green, and blue, of particles of intermediate sizes.

Having given a general view of the Newtonian theory of colours, as they depend upon the refraction of light, under the article COLOUR, we shall here add some farther particulars on this subject. From a review of that article, and of what has been above delivered, we may infer that, as the rays of light differ in refrangibility, they also differ in their disposition to exhibit this or that particular colour; so that colours are not modifications of light, derived from refractions or reflections of natural bodies, but original and connate properties, which are different in different rays. Moreover, to the same degree of refrangibility always belongs the same colour, and to the same colour the same degree of refrangibility; nor are the same species of colour, and degree of refrangibility, that are proper to any particular kind of rays, susceptible of change by refraction and by reflection of natural bodies, nor by any other cause which sir Isaac Newton could observe. Although a seeming transmutation of colours may be made by a mixture of different kinds of rays, yet, in such mixtures, the component colours themselves do not appear; but, by their mutually allaying each other, constitute a middle colour: and, therefore, if, by refraction, the different rays be separated, colours will emerge different from that of the composition. Thus blue and yellow powders, finely mixed, appear green to the naked eye; and yet the colours of the component particles are not thereby really changed, but only blended: for when they are viewed with a microscope, they still appear blue and yellow. It appears that there are also two sorts of colours: the one original and simple; the other compounded of these. The original and primary colours are red, orange, yellow, green, blue, indigo, and a violet purple, and an indefinite variety of intermediate gradations. The same colours in specie with those primary ones may be also produced by a composition: thus a mixture of yellow and blue makes green; of red and yellow, orange; and of orange and yellowish-green, yellow. In general, if any two colours are mixed, which, in the series of those that are produced by the prism, are not too far distant from one another, they, by their mutual alloy, compose that colour which appears in the midway between them; but those which are situated at too great distance have not this effect: *e. gr.* orange and indigo do not produce the intermediate green, nor scarlet and green the intermediate yellow.

The most wonderful composition is that of whiteness, which no one sort of rays alone can exhibit, but which is always compounded; so that all the aforesaid primary colours, mixed in a certain proportion, are necessary to form it. See COLOUR.

Having shewn, in the preceding part of this article, the extremes of the different degrees of refrangibility in the different kinds of light, we shall now proceed to give the result of Newton's investigation, concerning the different degrees of refrangibility of all the different kinds of light, according to their several colours; particularizing this part of the subject with an explanation of the method which he made use of to define the boundaries of each colour, in the oblong image of the sun above described. In that image, though there was a manifest difference of colour, not only between the two extremes, but also in the intermediate parts, yet the exact place at which any one colour ended, and another began, was far from being sufficiently distinguishable.

REFRANGIBILITY.

guishable. The reason of this indistinctness is, that rays of every kind coming from all parts of the sun's disc, an entire image of the sun is projected on the paper, consisting of a circle of each particular colour; and as the rays differ in kind by infinitesimal degrees, from the extreme red to the extreme violet, there mult, in fact, be thousands of these circles in the same oblong image, the centres of which are infinitely near to one another; so that the light is intimately mixed, especially in the middle of the image, where it is the brightest.

If these circles, as he observes, whilst their centres keep their distances and positions, could be made less in diameter, their interfering one with another, and consequently the mixture of heterogeneous rays, would be proportionably diminished. Thus, in *PT*, (*fig. 10.*) the circles of which the solar image consists, expand into one another; but in the same figure, *pt*, being composed of less circles, but having their centres at the same distance as the former, do not extend into one another, the mixture being diminished in proportion to the diameters of the circles.

Now these circles would be diminished, if, without the room, at a great distance from the prism, towards the sun, some opaque body was placed, having a round hole in the middle of it, to intercept all the sun's light, excepting so much as, coming from the middle of its disc, could pass through that hole to the prism; for so the separate circles would no longer answer to the whole disc of the sun, but only to that part of it which can be seen from the prism, through that hole. But that these circles may answer more distinctly to the hole, a lens is to be placed by the prism, to cast the image of the hole, that is, of each separate circle, distinctly upon the paper; and if this be done, it will not be necessary to place that hole very far off, not even beyond the window. Instead, therefore, of that hole, he made use of the hole in his window-shutter, in the following manner.

At about 10 or 12 feet from the window, he placed a lens, by which the image of the hole might be distinctly cast upon a sheet of white paper, at the distance of 6, 8, 10, or 12 feet from the lens. Then, immediately after the lens, he placed a prism, by which the refracted light might be thrown upwards, or sideways; and he moved the paper that received it, either towards the prism, or from it, till he found the exact distance at which the sides of the image appeared most distinct. By this means the circular images of the hole were terminated most distinctly, without any penumbra, and therefore extended into one another the least that they could; and consequently the mixture of the heterogeneous rays was the least of all. And by using a greater or less hole in the window-shutter, he made the circular images greater or less at pleasure, and thereby the mixture of rays in the oblong image was as much or as little as he chose. He sometimes made the breadth of the image 40 times, and sometimes 60 or 70 times less than its length. In this manner, he says, light is made sufficiently simple, and homogeneous, for trying any of his experiments about simple light; for that the heterogeneous rays in this light are so few, as hardly to be perceived, excepting, perhaps, in the indigo and violet, which, being dark colours, do easily suffer a sensible alloy by that little scattering light, which used to be refracted irregularly by the inequalities of the prism. The whole process of this experiment is so evident, by inspection of *fig. 11*, that it needs no particular illustration.

Instead of a circular hole, our author recommends a hole shaped like a long parallelogram, with its length parallel to the prism. For if this hole be an inch or two long, and

but a 10th or 20th part of an inch broad, or narrower, the light of the image will be as simple as before, or more simple, and the image will become much broader, and therefore more fit for these experiments.

Or, instead of this hole, another may be formed of a triangle of equal sides, whose base may be about the 10th part of an inch, and its height an inch or more. For, by this means, if the axis of the prism be parallel to the perpendicular of the triangle, the image *pt* (*fig. 12.*) will now be formed of equicrural triangles, *ag, bh, ci, dk, el, fm,* &c. and innumerable other intermediate ones, answering to the triangular hole in shape and bigness, and lying one after another in a continual series, between two parallel lines, *af, gm*. These triangles are a little intermingled at their bases, but not at their vertices; and therefore the light on the brighter side, *af*, of the image, where the bases of the triangles are, is a little compounded, but on the darker side, *gm*, it is altogether uncompounded; and in all places between the sides, the composition is proportionable to the distances of the places from that obscurer side *gm*; and having an image of such a composition, we may try experiments either in its stronger and less simple light, near the side *af*; or in its weaker and more simple light, near the other side *gm*, as shall seem most convenient.

In making these experiments, he advises, that the chamber be made very dark, that the lens be very good, being made of glass free from bubbles and veins, the sides of the prism truly plane, and its polish elaborate, with an angle of about 65 or 70 degrees; and the edges of the prism and lens, as far as they make any irregular refraction, should be covered with black paper glued on them. He also observes, that all the useless light should be intercepted with black paper, or other black obstacles. It being difficult to get glass prisms fit for these nice experiments, he sometimes used prismatic vessels made with pieces of broken looking-glasses, and filled with rain-water; and to increase the refraction, he sometimes strongly impregnated the water with *saccharum saturni*.

When he had, by this means, got the sides of the coloured image, as *AF, GM*, (*fig. 13.*) distinctly defined, he delineated on paper the outlines of it *FAPGMT*, and held the paper so that the image might fall on this figure, and coincide with it exactly; whilst an assistant, whose eyes could distinguish colours better than his own, did, by right lines drawn cross the image, mark the confines of each colour; and this operation being frequently repeated, both on the same and on different papers, he found that the observations agreed well enough with one another, and that the sides, *MG* and *FA*, were by this means divided like a musical chord; so that if *GM* were produced to *X*, making *MX* equal to *GM*, and if *GX, IX, iX, bX, eX, gX, aX, MX*, were in proportion to one another, as the numbers 1, $\frac{2}{3}$, $\frac{1}{2}$, $\frac{2}{3}$, $\frac{3}{4}$, $\frac{2}{3}$, $\frac{1}{6}$, and $\frac{1}{2}$, and so represented the chords of the key, and of a tone, a third minor, a fourth, a fifth, a sixth major, a seventh, and an eighth above that key. And the intervals *Ma, ag, ge, eb, bi, il*, and *IG*, were the spaces which the several colours, red, orange, yellow, green, blue, indigo, and violet, took up.

Now these intervals or spaces, subtending the differences of the refractions of the rays, going to the limit of those colours, that is to the points *M, a, g, e, b, i, l, G*, may, without any sensible error, be accounted proportional to the differences of the sines of refraction of those rays, having one common sine of incidence; and, therefore, since the common sine of incidence of the most and least refrangible rays, out of glass into air, was found in proportion to their sines of refraction as 50 to 77 and 78; if the difference between

REFRANGIBILITY.

tween 77 and 78 be divided, as the line *GM* is divided by those intervals, there will be 77, $77\frac{1}{2}$, $77\frac{2}{3}$, $77\frac{3}{4}$, $77\frac{4}{5}$, $77\frac{5}{6}$, 78, for the lines of refraction of those rays out of glass into air, their common sine of incidence being 50. So then the sines of the incidences of all the red-making rays out of glass into air were to the sines of their refractions not greater than 50 to 77, nor less than 50 to $77\frac{1}{2}$; but they varied from one another according to all their intermediate proportions, and so of the other colours.

Having demonstrated that the light of the sun consists of a certain proportion of differently coloured light, our author proves, by another series of experiments, what has been already demonstrated by a single one mentioned above, that when a beam of light has been divided into its component parts, if they be again mixed, they will produce white; or if any one of them be intercepted, the image will appear tinged, and in a different manner, according to the different colours that are thereby prevented from mixing with the rest: and to complete the whole, he observes, that intercepting all the colours that compose the white image except one, and thereby making it to exhibit the appearance of all the colours in order; yet, if he made this succession of all the colours very quick, the appearance was always white, though it was demonstrable that only one colour took place at any one time; and he justly observes, that if each of these colours in succession give the idea of whiteness, much more will they produce that effect, when they are so intimately mixed as they are in a natural sun-beam.

Not content with composing whiteness from the separately coloured rays of the sun, he attempted, and succeeded in his attempt, to do the same with natural coloured bodies, observing the same proportions of the respective colours that he had found in the solar image. The coloured powders which he made use of at first produced only a kind of grey; but this was in fact a dull white, or whiteness mixed with shade: for when he contrived to throw a very strong light upon it, it became intensely white, so that a friend of his, who happened to call upon him while he was busy about these curious experiments, and who knew nothing of what he had been doing, pronounced that the powders he had been mixing, when thus illuminated, made a better white than some very fine white paper, with which he was comparing it.

As the preceding proportion of all the prismatic colours makes a white, it is evident that when they are mixed in different proportions, or when only a few of them are used, they will make different colours; and our philosopher has given us the following ingenious method of knowing, in a mixture of primary colours, the quantity and quality of each being given, the colour of the compound. With the centre *O*, (*fig.* 14.) and the radius *OD*, describe a circle *ADF*, and divide the circumference into seven parts, proportional to the seven musical tones or intervals contained in an octave, that is in proportion to the numbers $\frac{1}{2}$, $\frac{2}{3}$, $\frac{3}{4}$, $\frac{4}{5}$, $\frac{5}{6}$, $\frac{6}{7}$, $\frac{7}{8}$. Let the first, *DE*, represent a red colour, the second, *EF*, orange, and so of the rest; and let all these colours be supposed to pass gradually into one another. Let *p* be the centre of gravity of the arc *DE*, and *q*, *r*, *s*, *t*, *u*, *x*, be the centres of gravity of the other arcs; and about those centres let circles, proportional to the number of rays of each colour in the given mixture, be described. Then find a common centre of gravity of all those circles; and if a line be drawn from the centre of the circle *O*, through this point, as suppose at *z*, the point *Y*, in which it terminates at the circumference, will shew the colour that arises from the mixture; and the line *OZ* will be proportioned to the fullness or intenseness of the colour, the centre

O representing perfect white. But if only two of the primary colours, which in this circle are opposite to one another, be mixed in an equal proportion, the point *Z* will fall upon the centre *O*, and yet the colour compounded of those two will not be perfectly white, but some faint anonymous colour; for he could never, by mixing only two primary colours, produce a perfect white. Whether it might be the result of three taken at equal distances in the circumference he could not tell; but he did not much question, but that four or five of them would be sufficient. These, however, as he observes, are curiosities of little or no moment to the understanding of the phenomena of nature, since, in all natural whites, there is a mixture of all kinds of rays. Newton's Optics. Priestley's Hist. of Light and Colours.

For the method of correcting the effect of the different refrangibility of the rays of light in glasses, see *ABERRATION* and *TELESCOPE*; see also *DISPERSION of Light*.

REFRANGIBILITY of Radiant Heat. See *RAYS of Heat*. Radiant heat, as well as light, is not only refrangible, but it is also subject to the laws of the dispersion, arising from its different refrangibility. The prism refracts radiant heat, so as to separate that which is less efficacious from that which is more so. The whole quantity of radiant heat contained in a sun beam, if this different refrangibility did not exist, must inevitably fall uniformly on a space equal to the area of the prism; and if radiant heat were not refrangible at all, it would fall upon an equal space, in the place where the shadow of the prism, when covered, may be seen. But neither of these events taking place, it is evident that the radiant heat is subject to the laws of refraction, and also to those of the different refrangibility of light. Whence Dr. Herschel is led to surmise, that radiant heat consists of particles of light of a certain range of momenta, which range may extend a little farther, on each side of refrangibility, than that of light. (See *RAYS of Heat*.) Dr. Herschel having found that two degrees of heat were obtained from that part of the prismatic spectrum which contained the violet rays, while the full red colour, on the opposite side, gave no less than seven degrees, infers from these facts the different refrangibility of the rays which occasion heat, as clearly and certainly as it is concluded that the refrangibility of light is ascertained by the dispersion and variety of the colours. But he proceeds farther, and observes, that the rays of heat are of a much more extensive refrangibility than those of light. In order to make this appear, he delineates a spectrum of light, by assuming a line of a certain length; and, dividing it into seven parts, according to the dimensions assigned to the seven colours by Sir Isaac Newton, in the fourth figure of the second part of his Optics, represents the illuminating power of which each colour is possessed, by an ordinate drawn to that line. And here, as the absolute length of the ordinates is arbitrary, provided they be proportional to each other, he assumes the length of that which is to express the maximum, equal to $\frac{2}{3}$ of the whole line.

Thus, let *GQ* (*fig.* 15.) represent the line that contains the arrangement of the colours, from the red to the violet. Then, erecting on the confines of the yellow and green the line *LR* = $\frac{2}{3}$ of *GQ*, it will represent the power of illumination of the rays in that place. For, by experiments already delivered, we have shewn that the maximum of illumination is in the brightest yellow or palest green rays. From the same experiments we collect, that the illuminations of yellow and green are equal to each other, and not much inferior to the maximum; this gives us the ordinates *K* and *M*. Then, by the rest of the same experiments, we obtain also the

the ordinates H, I, N, O, P, with sufficient accuracy for the purpose here intended. All these being applied to the middle of the spaces which belong to their respective colours, we have the figure G R Q G, representing what may be called the spectrum of illumination.

We are now, in the same manner, to find a figure to express the heating power of the refracted prismatic rays, or what may be called the spectrum of heat. In order to determine the length of the base, Dr. Herschel examined the extent of the invisible rays, and found, that at a distance of two inches beyond visible red, his thermometer, in a few minutes, acquired $1\frac{1}{4}$ degree of heat. The extent of the coloured spectrum at that time, or the line which answered to G Q in his figure, measured 2.997 inches. If two inches had been the whole of the extent of the invisible part, it might be stated to be in proportion to the visible one as 2 to 3; but we are to make some allowance for a small space required beyond the last ordinate, that the curve of the heating power drawn through it may reach the base; and indeed, at $2\frac{1}{4}$ inches beyond visible red, Dr. Herschel could still find $\frac{1}{2}$ degree of heat. It appears therefore sufficiently safe, to admit the base of the spectrum of heat A Q, to be to that of the spectrum of light G Q, as $5\frac{1}{4}$ to 3; or, conforming to the Newtonian figure before mentioned, the base of which is 3.3 inches, as $57\frac{3}{4}$ to 33. Now, if we assume for the maximum of heat, an ordinate of an equal length with that which was fixed upon for the maximum of light, it will give us a method of comparing the two spectra together. Accordingly, Dr. Herschel has drawn the several ordinates B, C, D, E, F, G, H, I, K, L, M, N, O, P, of such lengths as, from experiments made on purpose, it appeared they should be, in order to express the heat indicated by the thermometer, when placed on the base, at the several stations pointed out by the letters.

A mere inspection of the two figures, which have been drawn as lying upon one another, will enable us now to see how very differently the prism disperses the heat-making rays, and those which occasion illumination, over the areas A S Q A, and G R Q G, of our two spectra! These rays neither agree in their mean refrangibility, nor in the situation of their maxima. At R, where we have most light, there is but little heat; and at S, where we have most heat, we find no light at all!

REFRESHMENT, *Quarters of*. See **QUARTERS**.

REFRET, *Fr.* the burden of a song. This word is only to be found in the second folio edition of Bailey's Dictionary, 1736. In no French dictionary is there authority for it. Cotgrave, *Dict. du Vieux Langage*; Tre-voux, *Dict. de l'Académie*; and Glossaries, have been consulted in vain.

REFRIGERANT, **REFRIGERATIVE**, in *Medicine*, or *cooling*, from *frigus*, *cold*, an appellation given to such remedies as were supposed to possess a power of cooling the internal parts. Hence all diluents, such as ptilan, gruel, and other thin drinks, vegetable and mineral acids, neutral salts, and other substances, which are destitute of stimulating qualities, and communicate a sensation of coolness to the tongue and throat, have been considered as refrigerant. As they have no actual power of generating cold in the animal body, the term is somewhat incorrect; but as it expresses the opposite quality to that of stimulating, which is used also as synonymous with *heating*, it is still retained, and applied to diet, drink, and medicine of a non-stimulant quality. In this sense, the term is nearly synonymous with *sedative*.

Whatever, in fact, increases the circulation, increases the heat of the body, and *vice versa*; potentially, therefore,

all sedative medicines may be said to be refrigerant. The use of refrigerants will thence be inferred to be proper in all those cases in which there is an over-excitement of the circulation, either locally or generally; such as local inflammations, febrile diseases, hemorrhages, and the like. In the case of external inflammations, indeed, actual refrigeration may be produced, by the application of cold substances, water or ice, or by the abstraction of heat by means of evaporation; both of which afford the means of directly diminishing the activity of the vessels of the part. Thus, in burns and scalds, the pain is instantly relieved, and the inflammation effectually reduced, by the immersion of the part in cold water, if sufficiently persevered in. But in respect to internal refrigerants, their operation is of a negative kind, and consists rather in the removal of uneasy sensations, and in the exclusion of stimulant substances, than in the actual suppression of increased action. See **SEDATIVE**.

REFRIGERATION, denotes the act of cooling, or the abstraction of heat from various substances. This is effected in a variety of ways, and for various purposes of domestic use and of art; and the degree of cold that is produced is estimated by an instrument called the *thermometer*, which see. Under this head it is needless to repeat the principles of refrigeration, and the different processes that are used for this purpose, which are amply stated and described under the articles **COLD**, **CONGELATION**, **COOLING**, **FREEZING**, **HEAT**, **ICE**, **ICE-houses**, &c.

REFRIGERATORY, **REFRIGERATORIUM**, in *Chemistry*, a copper vessel filled with cold water, soldered round the capital of an alembic, to cool and condense the vapours raised thither by the fire, and to convert them into a liquor, to be discharged thence through the beak. See **ALEMBIC**.

The water in the refrigeratory is to be changed from time to time, as it begins to grow warm.

Sometimes they content themselves with wrapping a wet cloth about the head of the alembic, instead of a refrigeratory; but the more usual method now is, to supply the place of the refrigeratory by a worm, or spiral pipe, running through a tub of cold water.

Distillation chiefly consists in evaporation and refrigeration. See **DISTILLATION**.

REFUGE, **REFUGIUM**, in our *Old Customs*, a *sanctuary*, or *asylum*; which see respectively.

At Paris there is an hospital called the *Refuge*, in which dissolute women are shut up.

REFUGE, *Cities of*, in *Scripture History*, six cities selected from the 48 appropriated to the residence of the Levites, which were appointed for the protection of persons from the rigour of the law, who were chargeable with involuntary homicide. Some have supposed that all the cities of the Levites were asylums; but it appears from Numb. xxxv. 6. that only six of them were appointed to this use. These asylums were intended not only for Jews, but for Gentiles, or for strangers who dwelt among them. (Numb. xxxv. 15.) They were not designed as sanctuaries for wilful murderers and all sorts of atrocious villains among the Jews, as they were among the Greeks and Romans, and as such places have since been in Roman Catholic countries, but merely for securing those who had been guilty of involuntary homicide (Deut. xix. 4—10.) from the effects of private revenge, until they were cleared by a legal process. It is observable, that the Israelites are commanded to "prepare the way," that is, to make the road good, "that every slayer may flee thither," without impediment, and with all expedition. (Deut. xix. 3.) By having good roads to them, at least 32 cubits, or about 48 feet in breadth, and bridges wherever

wherever they were necessary, these cities were to be easy of access; and at cross roads posts were erected with inscriptions, directing the way to the "city of refuge." Upon this Hottinger remarks, that it was probably in allusion to this custom, that John the Baptist is described as "the voice of one crying in the wilderness, prepare ye the way of the Lord, make his paths straight." (Luke, iii. 4—6.) He was the Messiah's forerunner, and in that character was to remove the obstacles to men's flying to him as their asylum, and obtaining σωτηριον του θεου, the salvation of God. Every year, on the 15th of Adar, (February,) the magistrates were to inspect the roads, and ascertain their good condition. These cities were to be supplied with water and provisions; but they were not to be the residence of any artists who made weapons, by the use of which the relations of the deceased might gratify their revenge. It was necessary that those who took refuge in these places should understand some occupation, that might prevent their being chargeable, whilst they were waiting for their trial. In order to excite and maintain the greater horror even of involuntary bloodshed, the law punished it by a kind of banishment, for the accused person was to remain in this city, without departing from it, till the death of the high-priest, but after the high priest's death, he might safely go wherever he pleased.

REFUGÉES, French Protestants, who, by the revocation of the edict of Nantes, in 1685, have been constrained to quit their country, and retire for refuge into Holland, Germany, England, &c. to save themselves from the necessity of abandoning their religion.

REFUGIO, EL, in *Geography*, a harbour in one of the islands of Mayorga, where Maurelle was supplied with water in 1781, and which, he says, affords shelter from the most furious winds. S. lat. 18° 36'. E. long. 177° 32'.

REFVINGE, a town of Sweden, in the province of Halland; nine miles N.N.W. of Helsingstad.

REFUSAL, in *Law*, is where one hath by law a right and power of having or doing something of advantage to him, and he declines it. An executor may refuse an executorship: but the refusal ought to be before the ordinary; if an executor be summoned to accept or refuse the executorship, and he doth not appear upon the summons and prove the will, the court may grant administration, &c. which shall be good in law till such executor hath proved the will; but no man can be compelled to take upon him the executorship, unless he hath intermeddled with the estate. (1 Leon. 154. Cro. Eliz. 858.) Where there are several executors, and they all refuse, none of them shall administer afterwards; but if there is a refusal by one, and the other proves the will, the refusing executor may administer when he will, during the life of his co-executor. (1 Rep. 28.) If there is but one executor, and he administers, he cannot refuse afterwards, and if once he refuse, he cannot administer afterwards.

There is a refusal of a clerk presented to a church, for want of literature, &c. and if a bishop once refuses a clerk for insufficiency, he cannot accept of him afterward, if a new clerk is presented. (5 Rep. 58. Cro. Eliz. 27.) In action of trover and conversion, a demand of the goods, and refusal to deliver them must be proved, &c. 10 Rep. 56.

REFUTATION, REFUTATIO, in *Rhetoric*, that part of the answer made to an opponent, which disproves what had been advanced by him.

REGA, in *Geography*, a river of Pomerania, which rises three miles N.W. of Dramburg, passes by Regenwalde, Plate, Griessenberg, Treptow, &c., and then runs into the sea, 12 miles S.W. of Colberg.

REGAH, a town of Egypt, on the left bank of the Nile; six miles N. of Atfiel.

REGAL, REGIUS, or *Regalis*, something belonging to a king. Regal is of the same import with royal; the former being formed of the Latin *rex*; the other of the French *roy, king*.

REGAL, Fr., a musical term, which the Encyclopédie defines, "fiffl, an ancient instrument composed of many sticks of sonorous wood of different lengths, forming a scale, played upon by an ivory ball fastened to the end of a stick." This is exactly the description of the sticcado, said to be invented by the brother of Bremner, the late music-feller in the Strand, who published a book of instructions for playing upon it.

"Regal is, *secondly*, a spinet organized, or rather a small organ of two or three stops placed under a keyed instrument, very common in Spain and Italy. In France this kind of instrument is called a *positif*." Craing, an organ-builder in London about the middle of the last century, furnished organs of this kind to many harpichords and spinets in a virginal form. Snetzler, when he first came hither from Strasburg, was employed by Shudi to organize his harpichord.

But regal in all Roman Catholic countries is a portable organ used in processions, carried by one person and played by another. We have seen that use made of this kind of organ at Naples. The pipes are of reeds, for the lightness of carriage.

In the list of Edward VI. and queen Elizabeth's musical establishments in the Sloane MSS. at the British Museum, among the instrument-makers, the regal-maker is allowed 20*l.* yearly. And in our own memory there was an office in the chapel royal under the title of "tuner of the regals;" but it was abolished, and united to some more useful officer in the chapel.

In the supplement to the folio Encyclopédie, we are told that the regal is a portable organ, which has no pipes, or at most such as are very short, the tones being produced by reeds. This we believe to be the truth. The instrument is sometimes so small as to be set on a table.

REGAL Fijfl. See **ROYAL Fijfl.**

REGAL Suit. See **SUIT.**

REGALE, in the French *Jurisprudence*, is a right belonging to the king over all benefices in that kingdom.

The regale consists in enjoying the revenues of bishoprics, during the vacancy of their sees, and of presenting to the benefices dependent on them, which become vacant during that time, and till such a successor have taken the oath of fidelity, and have procured letters patent, to secure him from the regale.

The enjoyment of the fruits of the see is called the *temporal regale*; that of presenting the benefices, the *spiritual regale*.

Some refer the origin of the regale to the time of Clovis; and say, the clergy granted this privilege to the king upon his defeating the Visigoths; others allege, that pope Hadrian I. gratified Charlemagne with it, in a council held at Rome. It is observed by others, that the regale was originally no more than a ward, or administration; and that the kings were only depositaries of the fruits of the vacant bishoprics; and appointed œconomi to look to them during the vacancy.

It is added, that the kings of the first and second race never enjoyed any such privilege; and that it was only introduced in the twelfth century, in favour of investitures.

Whatever was the origin of the regale, it occasioned a

very important and warm debate between Lewis XIV. and pope Innocent XI. which began about the year 1678, and was carried on with great animosity and contention for several years after. Lewis was desirous, that all the churches in his dominion should be subject to the regale. Innocent pretended, on the contrary, that his claim could not be granted with such universality; nor would he consent to any augmentation of the prerogatives of this nature that had formerly been enjoyed by the kings of France. Lewis summoned, for settling this dispute, the famous assembly of thirty-five bishops, and as many deputies of the second order, which met at Paris in the year 1682, and which extended the regale to all the churches in France, without exception. In this convocation the ancient doctrine of the Gallican church, that declares the power of the pope to be merely spiritual, and also inferior to that of a general council, was drawn up in four propositions, which were solemnly adopted by the whole assembly, and were proposed to the whole body of the clergy, and to all the universities through the kingdom, as a sacred and inviolable rule of faith.

REGALE, *Regalia*, a magnificent treat, or entertainment, given to ambassadors, or other persons of distinction, to entertain or do them honour.

In Italy it is usual at the arrival of any traveller of eminence, to send him a regale, that is, a present of fruits, sweetmeats, &c. by way of refreshment.

REGALIA, in *Law*, the royal rights or prerogatives of a king.

These are reckoned by civilians to be six. 1. Power of judicature. 2. Power of life and death. 3. Power of war and peace. 4. Masterless goods, as waifs, estrays, &c. 5. Assessments. 6. Minting of money.

REGALIA is also used for the several parts of the apparatus of a coronation: as the crown, the sceptre with the cross, sceptre with the dove, St. Edward's staff, four several swords, the globe, and the orb with the cross, &c. used at the coronation of our kings.

REGALIA of the Church, are those rights and privileges which cathedrals, &c. enjoy by grants, and other concessions of kings.

Regalia is sometimes also used for the patrimony of a church; as, *regalia Sancti Petri*. And more particularly, for such lands and hereditaments as have been given by kings to the church.

"*Cæpimus in manum nostram baroniam et regalia quæ archiepiscopus Eborum de nobis tenet.*" Pryn. Lib. Ang.

These regalia, while in possession of the church, were subject to the same services as all other temporal inheritances; and after the death of the bishop they reverted to the king, till he invested another with them; which, in the reigns of William the Conqueror, and some of his immediate successors, was frequently delayed, and as oft did the bishops make complaint of it, as appears from Malmshury, Neubrigensis, &c.

This last author says, that great complaint was made against Henry II. "*Quod episcopatus vacantes, et provementia perciperet commoda, diu vacare voluit, et ecclesiasticis potius usibus applicanda in siccum redegit.*"

REGALIA Facere is used for the bishop's doing homage, or fealty, to the king, when he is invested with the regalia. Thus Malmshury, in Anselm: "*Regalia pro more istius temporis faciens principi vii. kalend. Octobris Cantuariz assedit.*"

REGALITIES. See **ROYALTIES.**

REGAN, in *Geography*, a town of Persia, in the province of Kerman, and district of Nurmansheer, on the

frontier of Kerman to the east, which district is about 93 miles in length, and in breadth from 30 to 80. This district is bounded on the N. and S. by a range of mountains, those to the S. being covered with snow during the greater part of the year. The soil is fertile, the district populous, and well watered by streams from the mountains, and the climate hot in the plain, but cold on the mountains. The Afghans were lately expelled from this district by the Persians, who invited different tribes of Balouches to occupy the deserted villages.

Regan is a neat little town, surrounded by a mud wall, within which the cattle of the inhabitants are driven every night for protection. The fort is quadrangular, the walls high and in good repair, and flanked with bastions, with one gate, constantly guarded for preventing the entrance of strangers. The capital of Nurmansheer is Krook, which is the residence of the governor, and built in the same style as Regan, but larger, and surrounded by a deep ditch. Before the expulsion of the Afghans, a city, called Bumm, was considered as the frontier town of Persia in this quarter. This city is strongly fortified by a high mud wall, flanked with towers, surrounded by a deep and broad dry ditch, with one gate; and it has a bazar tolerably supplied with dates, milk, and fruit. The ruins of Bumm testify that it was formerly of much greater extent than it is at present. The fountains are said to have thrown water to an amazing height, and the gardens, which appear to have been walled in, and adorned with elegant summer-houses, produce the most delicious pomegranates. Kinneir's Geog. Memoir of the Persian Empire, 1813.

REGARD of the Forest, the oversight, or inspection, of it; or the office and province of the regarder; which is, to go through the whole forest, and every bailiwick of it, before the holding of the sessions of the forest, or justice-seat, to see and enquire of the trespasses in it, and for the survey of dogs. A court for this purpose is to be holden every third year. See **EXPEDITATION**, and **FOREST**.

"*Ad vivendum, ad inquirendum, ad certificandum, &c.*" See **REGARDER**.

REGARD is also used for the extent of the regarder's charge, *i. e.* for the whole forest; or all the ground that is parcel of it.

REGARDANT, in *Heraldry*, is understood of a lion, or other beast of prey, borne in a posture of looking behind him, with his face towards his tail.

Others apply it to a beast, which only shews the head, and some part of the neck, as moving from out of some division of the coat into another. He bears azure, three bends, or, in a chief, argent, charged with a lion regardant, gules.

REGARDANT Villain, or *Regardant to the Manor*, denotes an ancient servant or retainer to the lord; thus called, because charged to do all base services within the manor, to see the same freed of all filthy and loathsome things that might annoy it, &c. Coke upon Littleton, fol. 120.

REGARDER of a Forest, *Regardator Forestæ*, an ancient officer of the king's forest, whose business was every year, upon oath, to make a regard, *i. e.* to take a view of the forest limits; also to enquire of all offences and defaults committed by the foresters within the forest, and of all the concealments of them; and whether all the other officers did execute their respective duties or not.

Manwood refers this institution to king Henry II. but Spelman thinks the name, at least, was given since; and that they were the same with those officers called *custodes venaticis*.

REGATTA

REGATTA is a name given at Venice to a kind of exhibition on the water, in which the gondoliers contest for superiority in the art of rowing their gondolas.

A splendid entertainment, under this appellation, was exhibited on the Thames in 1775.

REGAU, in *Geography*, a town of Austria; 12 miles W. of Steyr.

REGE INCONSULTO, in *Law*, is a writ issued from the king to the judges, not to proceed in a cause which may prejudice the king, until he is advised. A *rege inconsulto* may be awarded, not only for the party to the plea, but upon suggestion of a stranger, on cause shewn that the king may be prejudiced by the proceeding, &c.

REGE *Querela Coram*. See *QUERELA*.

REGEL, or RIGEL, in *Astronomy*, a fixed star of the first magnitude, in Orion's left foot.

REGELSBRUN, in *Geography*, a town of Austria; seven miles N. of Brugg.

REGEN, a river which rises on the borders of Bohemia, and runs into the Danube, near Ratibon.—Also, a town of Bavaria, on the above-named river; 40 miles E. of Ratibon.

REGENERATED TARTAR. See *TARTAR*, *Regenerated*.

REGENERATION, in *Theology*, the act of being born again by a spiritual birth, or becoming a child of God: or it is that change of heart and life experienced by a person, who forsakes a course of vice, and sincerely embraces a life of piety and virtue.

When an infidel is converted, baptism is always administered as a sign of regeneration.

The term is also used to signify the change of state that takes place at the resurrection. Matt. xix. 28.

REGENSBURG, in *Geography*, a town of Switzerland, in the canton of Zurich, situated on a mountain, and surrounded with walls in the year 1687: it is the principal place of a bailiwick formerly subject to the dukes of Austria; 6 miles E. of Baden.

REGENSBURG. See *RATIBON*.

REGENSTAUF, a town of Bavaria, in the principality of Neuburg; seven miles N. of Ratibon.

REGENSTEIN, a town of Westphalia, in the bishopric of Halberstadt; seven miles W. of Quedlinburg.

REGENSTORF, or *Old Regensberg*, a bailiwick of Switzerland, in the canton of Zurich, which derives its name from that of an ancient castle, destroyed in 1443.

REGENT, REGENS, a person who governs a kingdom during the minority or absence or incapacity of a king.

In France, the queen-mother has the regency of the kingdom, under the title of *queen-regent*, while the king is a minor. Some have urged, that women, being incapable of succeeding to that crown, were incapable of the regency; but custom has declared in their favour.

REGENT is also used for a professor of arts and sciences, who holds a class, or set of pupils, in a college.

The foreign universities are generally composed of doctors, professors, and regents. Regent and scholar are relative terms. See *TUTOR*.

Regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c.; these of philosophy are rather called professors.

REGENWALDE, in *Geography*, a town of Hinder Pomerania, on the Rega; 30 miles N.N.E. of Stargard. N. lat. 53° 49'. E. long. 15° 24'.

REGERENDARIUS, among the Romans, an officer who subscribed and kept a register of all petitions presented to the præfect. Pitisc. in voc.

REGESTOLA, in *Ornithology*, a name used by some authors for the mattagefs, or larger butcher-bird, a very small hawk, not exceeding the size of a common thrush, but very fierce and voracious. See *LANIUS Excubitor*.

REGETZ, in *Geography*, a town of Hungary; 18 miles S. of Caschau.

REGGE, a river of Holland, which rises near Enschede, and after passing by Ghoer, Ryfen, &c. joins the Veclit near Ommens.

REGGIO, PIETRO, in *Biography*, a native of Genoa, who seems to have been the first Italian who gave our country a taste for the vocal refinements of his country. Before his arrival here, he had been in Spain, Germany, Sweden, and France. Besides refinements in florid song, he was much admired for his exquisite manner of accompanying himself on the lute. His first residence in England was at Oxford, where he published, in 1677, a small tract, entitled "A Treatise to sing well any song whatever." In 1684 his book of songs, in folio, the words chiefly from Cowley, appeared. We know not what were the taste and expression which rendered his vocal powers so captivating; but his airs are very dry and monotonous, and in as old an Italian taste as those of Lelli.

REGGIO, in *Geography*, a city of Italy, capital of the department of the Crostolo, and formerly of the duchy of Modena, the see of a bishop, suffragan of Bologna. It was founded by the Tuscans, and became a Roman colony under Lepidus the triumvir. It was destroyed by Alaric, and rebuilt by Charlemagne. Its number of convents is 16, and of inhabitants about 18,000. The cathedral contains many capital pictures and sculptures. The inhabitants of this city were the first of all the Italians, who in 1794 renounced their allegiance to their own sovereign, Hercules III., who fled to Venice, afterwards took up arms, and solicited the protection of Bonaparte. He took possession of the city, proclaimed the liberty of the inhabitants, and instituted a legislative committee, who took the oath of allegiance to the French republic. Reggio is the native place of the poet Ariosto; 14 miles W.N.W. of Modena. N. lat. 44° 41'. E. long. 10° 38'.

REGGIO, a sea-port town of Naples, in Calabria Ultra, situated on the straits of Messina. The inhabitants carry on manufactures of stockings, gloves, and waistcoats of thread or silk. This place is the see of an archbishop, founded by the patriarch of Constantinople, and contains two colleges and seven convents. The environs abound in oranges, citrons, mulberries, and grapes, with some sugar-canes. This town was called by the Greeks *Rhegion*, derived according to Diodorus from the Greek word *ρηγνυμι*, to break or tear, because Sicily was torn from Italy, either by the sea or an earthquake. It is very ancient, founded as some say by Jocalrus, son of Æolus, king of Lipari, who entertained Ulysses; or, according to others, by the Chalcidians, who came hither from Eubœa. The territory of the Rhegini was free and powerful, though sometimes governed by tyrants. In the Peloponnesian war they suffered much from their neighbours the Epizephyrian Locri, and were distracted by internal contentions. In the time of Dionysius the elder they were very powerful and asserted their liberty, refusing an alliance with that tyrant, who demanded a daughter of the city. When Pyrrhus waged war against the Romans, the latter sent a legion for the protection of Rhegium; but the soldiers murdered the citizens and seized on the city. After the war the insurgents were taken by the Romans, and put to death for their treachery and cruelty. St. Paul, on his journey to Rome, passed through this city. In the year 1783 it was almost totally destroyed

by an earthquake; 10 miles S.E. of Messina. N. lat. $38^{\circ} 6'$. E. long. $16^{\circ} 53'$.

REGGILO, a town of Italy, in the department of the Mincio; six miles E. of Guastalla.

REGHABILLE, a town of Africa, in the country of Wangara, situated on a lake. N. lat. $12^{\circ} 47'$. E. long. $18^{\circ} 19'$.

REGIA AQUA. See AQUA.

REGIA Via. See VIA.

REGIA Villa. See VILLA.

REGICIDE, REGICIDA, a king-killer. The term is also used for the act itself of murdering a king; of *rex*, king, and *caedo*, I slay.

Regicide is chiefly used with us in speaking of the persons concerned in the trial, condemnation, and execution, of king Charles I.

REGIFUGE, REGIFUGIUM, a feast held in ancient Rome on the sixth of the calends of March, *i. e.* on our 24th of February, in memory of the expulsion of their kings, particularly of Tarquin's flying out of Rome on that day. Some will have the feast to bear this name from the *rex sacrorum*, king of the sacrifices, flying out of the comitia, or place of assembly, as soon as the sacrifice was over, in imitation of the flight of Tarquin the Proud.

Some critics and antiquaries will have Regifugium the same with Fugalia; others hold them to be different.

REGIMEN, in *Medicine*, from *rego*, I rule or govern, a rule or course of living, with regard to eating, drinking, clothing, and the like, accommodated to some disease, or particular course of medicine which the patient is under, or intended as a prevention of some threatening malady.

In many diseases, especially those of the acute or febrile class, the regimen is often of equal, and sometimes of more importance than medicine: and there can be no doubt that the humoral physicians, by the introduction of a *hot* regimen in the treatment of febrile complaints, contributed to render these diseases more severe and fatal; and that the substitution of a cool regimen has of late years very materially diminished the danger and mortality of these maladies. This change in medical practice has been, in fact, but a return to nature, and to Hippocrates, who taught this simple, but clear and rational principle, "*contraria contrariis medentur*;" remedies should be of an opposite nature to diseases: that is to say, if the body is morbidly hot, cold is the remedy; if it is cold, the application of heat is necessary; if there is over-distention, inflammation, or plethora, evacuation must be resorted to: if depletion, we must supply nourishment: if there is thirst, the remedy is the free use of drink, and so forth. The clear instincts of nature (where they can be distinguished) are commonly infallible guides, as to the regimen to be pursued: but let not morbid habits and prejudices be mistaken for them. Thus in *all fevers*, small-pox, measles, scarlet-fever, catarrh, typhus, and the plague itself, the natural bias is for fresh air, coolness, light bed-clothes, clean linen, cold drink, light and merely liquid nourishment, in small quantities, or absolute abstinence, quietness of mind and body, relief from noise, strong light, and every species of excitement; and this is precisely the regimen, which experience has proved to be most beneficial in such diseases. Under the influence of such a regimen, where proper medicines are also employed, every symptom is rendered comparatively mild; the distress of the sick is diminished, by the soothing of every morbid sensation; and the derangements, which would otherwise ensue, or be aggravated, in the more vital organs, as in the brain, lungs, and alimentary canal, are frequently altogether prevented.

It is sufficient to contrast the effects of the hot regimen, in febrile diseases, to be convinced of the truth of these observations. When a person afflicted with any species of fever, is confined in a close and heated apartment, in which the free circulation of air is prevented by closed doors and windows, curtains, &c. and is kept at the same time under a load of bed-clothes, and supplied with hot drinks, or even cordials of vinous and fermented liquors, with the view of inducing perspiration, the consequences are as follow. The whole train of symptoms is aggravated. The heat of the patient is raised considerably above the natural standard, notwithstanding the profuse perspirations that are constantly bathing him; the pulse is excited to the highest febrile standard; the thirst becomes incessant to supply the unnatural waste of fluids; the mouth and lips become parched and furred; the head is in constant pain, with confusion of ideas, preventing all sound sleep, and occasioning distressing dreams, and at length delirium; the whole powers of the frame become prostrate, with disposition to fainting, on being moved, or on passing an evacuation by stool; and from this situation the recovery is extremely precarious. In cases of contagious fever, such as small-pox, measles, scarlet-fever, &c., the eruption is always greatly multiplied by this hot regimen, and all the symptoms are changed to what has been called a putrid type; the tongue, teeth, and lips, become coated with a black, clammy, and immovable fur; purple spots appear on the skin; and the whole disease assumes the character of malignancy. There is one disease, indeed, which is solely the result of this hot regimen, which has made a considerable figure in the writings of physicians, who never dreamt that it was of their own creation; we allude to the *miliary fever*. See MILIARIA.

The above may perhaps be considered as the extreme of the picture, which is scarcely ever to be seen in the present day. But the greatest difficulty which a physician has even now to overcome, in the majority of cases of febrile diseases, is to counteract the tendency of nurses and parents to the adoption of more or less of this pernicious system. The salutary *chill* must be taken away from all liquids, whether used internally or externally; the cheering breeze is deemed a death-bringing draught; and though the patient may die from the severity of a malignant fever, he must on no account run the slightest risk of *catching cold*; that is to say, the possible occurrence of a slight fore-throat, or a running at the nose, is to be avoided religiously, at the expence of aggravating both the sufferings and the danger, under a more formidable disease. The use of wine and cordials, in these diseases, is now confined to the poor and ignorant, and it is to be hoped, that the other parts of the hot regimen will not long be resorted to, at least among the more intelligent classes of society. See COLD as a remedy.

REGIMEN, in *Chemistry* and *Alchemy*, is the method of ordering and conducting any thing, that it may answer its intention.

Thus, regimen of fire is the method of making and ordering fire, and the degrees of it.

REGIMEN of the Work, that is, of the philosopher's stone, called the *work of patience*, is the rule and conduct to be observed to obtain protection.

There are three things, they say, to be chiefly regarded in the regimen of the work. The first, to administer a gentle easy heat at the beginning of the coction.

The second, to continue this external heat according to the season of the work, always observing four seasons, as in the common and astronomical year; the beginning being the winter, the progress the spring, then summer, and lastly autumn, which is the time of maturity and perfection of the stone;

REGIMEN.

stone; in all which the heat is to be augmented in proportion to the augmentation observed in nature.

It is to be added, that the work may not be begun in any season; but regard is to be had to the seasons of nature, lest the winter of the work be found in the summer of the year, &c. Which, however, is to be understood of the day in which the mercury is put in the ovum philosophicum, not of that when it is begun to be set at liberty from the prisons which nature had inclosed it in.

The third is, that in augmenting the fire, the augmentation be not of a whole degree at once, the spirits being unable to bear such violence; but a degree is to be divided into four parts, and one part is to be taken at a time.

All the operations of the first regimen are occult and invisible: in the second regimen comes putrefaction, which, they say, is the first sensible change, shewing itself by its black colour.

REGIMEN, or *Government*, in *Grammar*, is that part of syntax or construction, which regulates the mutual dependency of words, and the alterations which one part of speech occasions in another, with regard to its mood, tense, or case, and thus it differs from concord, or the agreement which one word has with another, in gender, number, case, or person. See CONCORD.

The regimen, or government, is entirely arbitrary, and differs in all languages; one language forming its regimen by cases, as the Latins and Greeks; others by particles in lieu of them, as the English by *of*, *to*, &c. the French, Spaniards, and Italians, by *de*, *a*, *da*, &c.

There are, however, some general maxims which hold good in all languages; as, 1. That there is no nominative case in any sentence but has a reference to some verb, either expressed or understood. Sometimes, indeed, the infinitive mood, or part of a sentence, is put as the nominative case to the verb; as in English, "to see the sun is pleasant." These sentences, or clauses, thus constituting the subject of an affirmation, may be termed "nominative cases."

2. That there is no verb, except in the infinitive mood, or the participle, but has its nominative case, either expressed or understood. Indeed, in languages which have proper accusatives, as the Latin, before infinitives there is an accusative, not a nominative case; as *Scio Petrum esse doctum*. The nominative case is commonly placed before the verb; but sometimes it is put after the verb, if it is a simple tense; and between the auxiliary and the verb, or participle, if a compound tense.

3. Two or more nouns, &c. in the singular number, joined together by one or more copulative conjunctions, expressed or understood, must have verbs, nouns, and pronouns, agreeing with them in the plural number. The conjunction disjunctive, however, has an effect contrary to that of the conjunction copulative; for as the verb, noun, or pronoun, is referred to the preceding terms, taken separately, it must be in the singular.

4. A noun of multitude, or signifying many, may have a verb or pronoun agreeing with it, either of the singular or plural number; but not without regard to the import of the word, as conveying unity or plurality of idea. In the application of this rule, we ought to consider whether the term immediately suggests the idea of the number it represents, or whether it exhibits to the mind the idea of the whole as one thing. In the former case, the verb ought to be plural; in the latter, it ought to be singular.

5. Pronouns must always agree with their antecedents, and the nouns for which they stand, in gender and number.

6. The relative is the nominative case to the verb, when

no nominative comes between it and the verb; but when a nominative comes between the relative and the verb, the relative is governed by some word in its own member of the sentence; *e. gr.* "he *who* preserves me, to *whom* I owe my being, *whose* I am, and *whom* I serve, is eternal."

7. When the relative is preceded by two nominatives of different persons, the relative and verb may agree in person with either, according to the sense.

8. Every adjective, and every adjective pronoun, belongs to a substantive, expressed or understood. Adjective pronouns must agree in number with their substantives; nevertheless this rule admits of exceptions; *e. gr.* the word *means* in the singular number, and the phrases "by this means," "by that means," are used by our best and most correct writers, *viz.* Bacon, Tillotson, Atterbury, Addison, Steele, Pope, &c. Campbell, in his "Philosophy of Rhetoric," has this remark on the subject before us: "No persons of taste will, I presume, venture so far to violate the present usage, and consequently to shock the ears of the generality of readers, as to say 'by this *mean*,' 'by that *mean*.'" Lowth and Johnson seem also to be against the use of *means* in the singular number. The distributive adjective pronouns, *each*, *every*, *either*, agree with the nouns, pronouns, and verbs of the singular number only. Adjectives are sometimes improperly applied as adverbs. An adjective pronoun, in the plural number, will sometimes properly associate with a singular noun. Although the adjective always relates to a substantive, it is, in many instances, put as if it were absolute, especially where the noun has been mentioned before, or is easily understood, though not expressed. Substantives are often used as adjectives; in this case, the word so used is sometimes unconnected with the substantive to which it relates; sometimes connected with it by a hyphen; and sometimes joined to it, so as to make the two words coalesce. Sometimes the adjective becomes a substantive, and has another adjective joined to it. When an adjective has a preposition before it, the substantive being understood, it takes the nature of an adverb, and is considered as an adverb.

9. One substantive governs another, signifying a different thing, in the possessive or genitive case; inasmuch as that case always expresses the possessor, which must be governed by the possessed: as, "my father's house," "virtue's reward," &c. When the annexed substantive signifies the same thing as the first, and serves merely to explain or describe it, there is no variation of case; as "George, king of Great Britain, elector of Hanover, &c." Nouns thus circumstanced are said to be *in apposition* to each other: and nouns are not unfrequently set in apposition to sentences, or clauses of sentences. This rule does not hold so apparently in the modern as it does in the ancient languages; because the particles *of*, *de*, &c. which are the proper signs of the genitive case, are frequently used as prepositions. (See GENITIVE.) Substantives govern pronouns as well as nouns in the possessive case; as "every tree is known by *its* fruit." Sometimes a substantive in the genitive or possessive case stands alone, the latter one by which it is governed being understood. The English genitive has often an unpleasant sound, so that we make more use of the particle *of* to express the same relation: and in some cases, we use both the genitive termination and the preposition *of*; as "it is a discovery of sir Isaac Newton's:" but when this double genitive, as some grammarians call it, is not necessary to distinguish the sense, and especially in a grave style, it is generally omitted. Except to prevent ambiguity, it seems to be allowable only in cases which suppose the existence of a plurality of subjects of the same kind, as "a subject of the emperors." But after all that can be said for the double genitive, as it is termed,

termed, it is the opinion of some grammarians, that it would be better to avoid the use of it altogether, and to give the sentiment another form of expression.

10. Active verbs govern the objective (or accusative) case, as "Virtue rewards her followers." In English, the nominative case, denoting the subject, usually goes before the verb; and the objective case, denoting the object, follows the verb active; and it is this order that determines the case in nouns; as, "Alexander conquered the Persians:" but the pronoun having a proper form for each of those cases, is sometimes, when it is in the objective case, placed before the verb; and when it is in the nominative case, follows the object and verb; as "whom ye ignorantly worship, him declare I unto you." Verbs neuter do not act upon, or govern, nouns and pronouns. Part of a sentence, as well as a noun or pronoun, may be said to be in the objective case, or to be put objectively, governed by the active verb; and sentences or phrases under this circumstance may be termed "objective sentences or phrases." The verb *to be*, through all its variations, has the same case after it as that which next precedes it; so that this substantive verb has no government, or case, but serves, in all its forms, as a conductor to the two cases, inasmuch that the two cases which, in the construction of the sentence, are the *next* before and after it, must always be alike. Passive verbs which signify naming, and others of a similar nature, have the same case before and after them; as "he was called *Cæsar*." It is evident also, that certain other neuter verbs, besides the verb *to be*, require the same case, whether it be the nominative or the objective, before and after them; such verbs are, to become, to wander, to go, to return, to appear, to die, to live, to look, to grow, to seem, to roam, and several others. The auxiliary *let* governs the objective case; as "let *him* beware."

11. One verb governs another that follows it, or depends upon it, in the infinitive mood; as, "cease *to do evil*," "learn *to do well*;" and the preposition *to*, though generally used before the latter verb, is sometimes properly omitted; as "I heard him say it," instead of "to say it." This irregularity extends only to active or neuter verbs: for many other verbs, when made passive, require the preposition *to* before the following verb; as "He was seen *to go*." The infinitive is frequently governed by adjectives, substantives, and participles; and this mood has much of the nature of a substantive, expressing the action itself which the verb signifies, as the participle has the nature of an adjective, so that the infinitive mood does the office of a substantive in different cases, as in the nominative, "to play is pleasant," and in the objective, "boys love *to play*." The infinitive mood is often made absolute, or used independently on the rest of the sentence, supplying the place of the conjunction *that* with the potential mood, as "to confess the truth, I was in fault." The preposition *to*, signifying *in order to*, was anciently preceded by *for*, as "what went ye out *for to see*;" but the word *for* before the infinitive, is now, in almost every case, obsolete.

12. In the use of words and phrases which, with respect to time, relate to each other, a due regard to that relation should be observed. Thus, instead of saying, "the Lord *hath given*, and the Lord *hath taken away*," we should say, "the Lord *gave*, and the Lord *hath taken away*." To preserve consistency in the time of verbs, and also of words and phrases, says Mr. L. Murray, in his excellent treatise on Grammar, we must recollect that, in the subjunctive mood, the present and the imperfect tenses often carry with them a future sense; and that the auxiliaries *should* and *would*, in the imperfect time, are used to express the present and future, as well as the past. With regard to verbs

in the infinitive mood, says the same popular author, the practice of many writers, among whom are some of the most respectable, appears to be erroneous. They seem not to advert to the true principles which influence the different tenses of this mood. The following rules will, according to our author's judgment, be found perspicuous and accurate. "All verbs expressive of hope, desire, intention, or command, must invariably be followed by the present, and not the perfect of the infinitive." Instead of the phrase, "the last week I intended to *have written*," though common, the infinitive being in the past time, as well as the verb which it follows, it ought to be, "the last week I intended *to write*:" for how long soever it now is since I thought of writing, "to write" was then present to me, and must still be considered as present, when I bring back that time, and the thoughts of it. Some writers on grammar, however, maintain that the former sentence is correct and grammatical, because, as they assert, it simply denotes the speaker's intention to be hereafter in possession of the finished action of writing; but this reasoning admits of the following answers, according to the statement of Mr. Murray. The phrase "to have written" is, in English grammar, the established past tense of the infinitive mood, and as incontrovertibly the past tense of the infinitive in English, as *scripsisse* is the past tense of the infinitive in Latin; nor can any writers be warranted in taking such liberties with the language, as to contradict its plainest rules, for the sake of supporting an hypothesis. Moreover, these writers might, on their own principles, and with equal propriety, contend, that the phrase "I intended *having written*," is proper and grammatical; but by admitting such violations of established grammatical distinctions, confusion would be introduced, the language would be disorganized, and the most eccentric systems of grammar might be advanced, and plausibly supported. In short, says our author, the phrase "I intended to have written," appears to involve the following absurdity; "I intended to produce hereafter an action or event, which has been already completed." Some may hastily infer from the rule above stated, and from the near relation between the verbs *to desire*, and *to wish*, that the latter verb, like the former, must invariably be followed by the present of the infinitive. But when any one considers, that the act of *desiring* always refers to the future, and that the act of *wishing* refers sometimes to the past, as well as sometimes to the future, he will perceive the distinction between them, and that, consequently, the following modes of expression are strictly justifiable: "I wished *that I had written* sooner," "I wished *to have written* sooner;" and he will be perfectly satisfied, that the following phrases must be improper: "I desired that I had written sooner," "I desired to have written sooner." Mr. Murray, having considered and explained the special rule, respecting the government of verbs, expressive of hope, desire, intention, or command, proceeds to state and elucidate the general rule, on the subject of verbs in the infinitive mood. "This rule," he says, "is founded on the authority of Harris, Lowth, Campbell, Pickbourn, &c.; and we think, too, on the authority of reason and common sense. "When the action or event, signified by a verb in the infinitive mood, is *contemporary* or *future*, with respect to the verb to which it is chiefly related, the present of the infinitive is required: when it is *not contemporary, nor future*, the perfect of the infinitive is necessary." To comprehend and apply this rule, the student has only to consider, whether the infinitive verb refers to a time antecedent, contemporary, or future, with regard to the governing or related verb. When this simple point is ascertained, there will be no doubt in his mind, respecting the form

form which the infinitive verb should have. A few examples may illustrate these positions. If I wish to signify, that I rejoiced at a particular time, in recollecting the sight of a friend, some time having intervened between the *seeing* and the *rejoicing*, I should express myself thus: "I rejoiced *to have seen* my friend." The *seeing*, in this case, was evidently antecedent to the *rejoicing*; and therefore the verb which expresses the former, must be in the perfect of the infinitive mood. The same meaning may be expressed in a different form: "I rejoiced *that I had seen* my friend;" or, "*in having seen* my friend;" and the student may, in general, try the propriety of a doubtful point of this nature, by converting the phrase into these two correspondent forms of expression. When it is convertible into both these equivalent phrases, its legitimacy must be admitted.—If, on the contrary, I wish to signify, that I rejoiced at the sight of my friend, that my joy and his presence were contemporary, I should say, "I rejoiced *to see* my friend;" or, in other words, "I rejoiced *in seeing* my friend." The correctness of this form of the infinitive may also, in most cases, be tried, by converting the phrase into other phrases of a similar import.

The subject may be still further illustrated, by additional examples. In the sentence which follows, the verb is with propriety put in the perfect tense of the infinitive mood: "It would have afforded me great pleasure, as often as I reflected upon it, *to have been* the messenger of such intelligence." As the message, in this instance, was antecedent to the pleasure, and not contemporary with it, the verb expressive of the message must denote that antecedence, by being in the perfect of the infinitive. If, on the contrary, the message and the pleasure were referred to as contemporary, the subsequent verb would, with equal propriety, have been put in the present of the infinitive: as, "it would have afforded me great pleasure, *to be* the messenger of such intelligence." In the former instance, the phrase in question is equivalent to these words; "*if I had been* the messenger;" in the latter instance, to this expression; "*being* the messenger."

To assert, as some writers do, that verbs in the infinitive mood have no tenses, no relative distinctions of present, past, and future, is inconsistent with just grammatical views of the subject. That these verbs associate with verbs in all the tenses, is no proof of their having no peculiar time of their own. Whatever period the governing verb assumes, whether present, past, or future, the governed verb in the infinitive always respects that period, and its time is calculated from it. Thus, the time of the infinitive may be before, after, or the same as, the time of the governing verb, according as the thing signified by the infinitive, is supposed to be before, after, or present with, the thing denoted by the governing verb. It is, therefore, with great propriety, that tenses are assigned to verbs of the infinitive mood. The point of time from which they are computed is of no consequence; since present, past, and future, are completely applicable to them.

It may not be improper to observe, that though it is often correct to use the perfect of the infinitive after the governing verb, yet there are particular cases, in which it would be better to give the expression a different form. Thus, instead of saying, "I wish to have written to him sooner," "I then wished to have written to him sooner," "He will one day wish to have written sooner;" it would be more periphrastic and forcible, as well as more agreeable to the practice of good writers, to say; "I wish that I had written to him sooner," "I then wished that I had written to

him sooner," "He will one day wish that he had written sooner."

13. Participles have the same government as the verbs from which they are derived; as, "I am weary with *hearing* him," &c. It should be considered, however, that participles are sometimes governed by the article; for the present participle, with the definite article *the* before it, becomes a substantive, and must have the preposition *of* after it. This rule arises from the nature and idiom of our language, and from as plain a principle as any on which it is founded; namely, that a word which has the article before it, and the possessive preposition *of* after it, must be a noun; and, if a noun, it ought to follow the construction of a noun, and not to have the regimen of a verb. It is the participial termination of this sort of words that is apt to deceive us, and make us treat them as if they were of an amphibious species, partly nouns and partly verbs.

The same observations, which have been made respecting the effect of the article and participle, appear to be applicable to the pronoun and participle, when they are similarly associated. When a substantive is put absolutely, and does not agree with the following verb, it remains independent on the participle, and is called the "case absolute," or the "nominative absolute;" but when the substantive preceding the participle agrees with the subsequent verb, it loses its absoluteness, and is like every other nominative.

14. Adverbs, though they have no government of case, tense, &c. require an appropriate situation in the sentence, *viz.* for the most part, before adjectives, after verbs active or neuter, and frequently between the auxiliary and the verb.

15. Prepositions govern the objective case. Under this rule we may remark, that the prepositions *to* and *for* are often understood, chiefly before the pronouns, as "give me the book," for *to me*, &c. The preposition is often separated from the relative which it governs; as "whom will you give it to?" for "to whom will you give it?" Some writers separate the preposition from the noun or pronoun which it governs, in order to connect different prepositions with the same word; but this kind of construction is always inelegant, and should generally be avoided. Different relations, and different senses, must be expressed by different prepositions, though in conjunction with the same verb or adjective. Thus we say, "to converse *with* a person, *upon* a subject, *in* a house, &c." When prepositions are subjoined to nouns, they are generally the same that are subjoined to the verbs from which the nouns are derived. Many writers, as Dr. Priestley has observed, affect to subjoin to any word the preposition with which it is compounded, or the idea of which it implies, in order to point out the relation of the words, in a more distinct and definite manner, and to avoid the more indeterminate propositions *of* and *to*: but general practice, and the idiom of the English tongue, seem to oppose the innovation. Thus many writers say, "averse *from* a thing;" but others use "averse *to* it," which is more truly English: "Averse *to* any advice," Swift. "The words *averse* and *aversion*," says Dr. Campbell, "are more properly construed with *to* than with *from*. The examples in favour of the latter preposition are beyond comparison outnumbered by those in favour of the former. The argument from etymology is here of no value, being taken from the use of another language. If, by the same rule, we were to regulate all nouns and verbs of Latin original, our present syntax would be overturned. It is more conformable to English analogy with *to*; the words *dislike* and *hatred*, nearly synonymous, are thus construed."

16. Conjunctions connect the same moods and tenses of verbs,

verbs, and cases of nouns and pronouns, as "Candour is to be approved and praised."

17. Some conjunctions require the indicative, some the subjunctive mood, after them. Those that are of a positive and absolute nature belong to the former class; *e. g.* "As virtue advances, so vice recedes." When something contingent or doubtful is implied, the subjunctive ought to be used, as "If I were to write, he would not regard it." See SUBJUNCTIVE.

18. When the qualities of different things are compared, the latter noun or pronoun is not governed by the conjunction *than* or *as*, but agrees with the verb, or is governed by the verb or the preposition, expressed or understood; as "Thou art wiser than I," that is, "than I am."

19. For the purpose of avoiding disagreeable repetitions, and of expressing our ideas in few words, an ellipsis, or omission of some words, is frequently admitted; *e. g.* instead of saying "He was a learned man, he was a wise man, and he was a good man," we say, availing ourselves of the ellipsis, "He was a learned, wise, and good man."

20. All the parts of a sentence should correspond to each other; so that a regular and dependent construction may, throughout, be carefully preserved. The following sentence is inaccurate; "He was more beloved, but not so much admired, as Cinthio," it should be, "He was more beloved than Cinthio, but not so much admired."

21. The regimen of verbs is frequently laid on different kinds of relations, according to custom or usage; which yet does not change the specific relation of each case, but only shews, that custom has made choice of this or that, according to fancy. Thus the Latins say, *juvare aliquem*, and *opitulari alicui*, to help one. So the French say, *servir quelqu'un*, and *servir à quelqu'un*, to serve one. Thus the English say, *fight one*, or *fight with one*. And thus, in Spanish, most of the verbs active govern indifferently either a dative or an accusative. Sometimes, also, the verb admits of several regimens; as *prestare aliquem*, or *alicui*; *eripere mortui aliquem*, or *alicui* à morte.

Indeed, the different regimen sometimes makes an alteration in the sense; in which, particular regard is to be had to the usage of the language. Thus, the Latin *cavere alicui* signifies to watch, or be careful of the preservation of any one; *cavere aliquem* signifies to beware of him.

There is one very common fault in regimen, which our accurate writers should be careful to avoid; *viz.* the using of two verbs that require different cases together, as only governing one case; as in this example; after *embracing and giving his blessing to his son*; where *embracing* requiring an accusative, and *giving* a dative case, the regimen or construction of the first verb with the noun is irregular; *embrace to a son*.

The same may be observed in nouns; as, *I conjured him by the memory and the friendship he bore my father*; where *memory* does not agree with *he bore*.

For an ample illustration of these rules by appropriate examples, and also of the exceptions which pertain to each respectively, we refer to Mr. Murray's English Grammar, vol. i. ch. 12. See CONCORD and SYNTAX.

REGIMEN, or *Construction, State of, Status regiminis*, a phrase used by Hebrew grammarians in contradistinction to the *absolute state*, or *status absolutus*. A noun in *status absoluto* is that which does not govern either a genitive or any oblique case; and it is said to be in *regimine* or in *constructione*, when it does govern such case. Nouns of the former kind seldom undergo any change in the letters that form them, as מלכים זרקים, just kings, whereas the latter either

lose one of their letters, or undergo a change of one into another; but these latter admit of excepted cases; *e. gr.* singular masculine nouns undergo no change in *regimine* מלך ארץ, king of the land, and plurals throw off the final letter, as מלכי ארץ, kings of the earth, for מלכים ארץ. This is also the case with participles, as פעל און, working iniquity, and פעלי און, workers of iniquity. Singular feminine nouns ending in ה change the ה in *regimine* into ת, as תורת יהוה, the law of the Lord; others, and especially plural nouns, undergo no change מלכת שמים, the kingdom of heaven. We shall here observe, that the change which takes place on account of the state of regimen is made in the governing noun, and not in that which is governed, contrary to the practice in other languages. For other particulars referring to regimen in Hebrew, as well as in Latin, Greek, and other learned languages, we refer to the article SYNTAX.

REGIMENT, derived from the Fr. *regie*, of *regere*, to govern, or from the Fr. *regime*, denoting system or administration, in *War*, a body consisting of several troops of horse, or companies of foot, commanded by a colonel, lieutenant-colonel, and major; or, as sir James Turner defines it, a certain number of companies joined in one body, under one head. A regiment of cavalry consists of one or more squadrons; and a regiment of infantry of one or more battalions.

The number of men in a regiment is as undetermined as that of the men in a troop, or company; in a squadron or battalion.

A battalion in each regiment of foot is divided into companies, but the number of companies is various; though, in England, our regiments are generally ten companies; two of which are called the flanks; one on the right, consisting of grenadiers, and another on the left, formed of light troops. The squadrons in cavalry, or in regiments of horse, are divided, sometimes into six, and sometimes into nine troops. Each regiment has a chaplain, quarter-master, adjutant, and surgeon. It has been suggested, that every regiment of foot should consist of 2400 men, making three battalions of 800 each.

Some German regiments consist of 2000 foot; and the regiment of Picardy in France consisted of 120 companies, or 6000 men.

The French have distinguished between the commanding officer of a regiment of cavalry, and the commanding officer of a regiment of infantry; the former having been called "maitre de camp," and the latter "colonel," as with us. According to the present establishment of the French army, the term "regiment" is confined to the cavalry and artillery, and the name of half brigade is given to the infantry, so that "chef de brigade," chief of brigade, corresponds with our colonel of a regiment of infantry. In the French cavalry the term colonel is still retained.

Some observe, that there were no regiments of horse before the year 1637. Till then the troops were loose and independent of each other, and not incorporated into a body or regiment.

Regiments, it is said, were first formed in France, under the reign of Charles IX. though F. Daniel refers them to the time of Henry II. and in England to the year 1660. Grose observes, that we may, without being very much mistaken, place the introduction of regiments and colonels about the reign of king Henry VIII.

We shall here annex a brief account of some of the principal regiments of the old corps. The first and second regiments of life-guards claim priority of notice. The life-

REGIMENT.

guards succeeded that body under the same denomination which was raised by Charles II., soon after the restoration, the privates of whom were taken from the cavalier gentlemen, who had adopted the profession of arms, and followed the fortunes of his father during the civil wars. As they were for the most part men of family, they possessed certain privileges, similar to those of the household troops in France, after whom they were modelled; and these privileges were continued long after the time when they ceased to be composed of the same class of men. It was, therefore, found necessary to reduce the privates, and to form a new corps, composed almost entirely of recruits under the old officers, and to place them nearly on the same footing with the rest of the cavalry; reserving for them, however, the advantages arising out of a higher pay, and an exemption from stoppages on the part of the privates, whose clothing is furnished by government. The life-guards claim the privilege, that their officers are not liable to be tried by any court-martial, unless the members are composed of their own regiment, or of officers of the other household troops. The first regiment of life-guards, consisting of very fine men, about 6 feet high at an average, was formed in 1788. The uniform is scarlet, faced with blue, and gold lace. The commissioned officers are a colonel, one lieutenant-colonel, one supernumerary lieutenant-colonel, two majors, five captains, six lieutenants, one adjutant and lieutenant, five cornets, one surgeon, and one veterinary surgeon. The non-commissioned officers consist of quarter-masters and corporals. The privates are about 260 in number. Their quarters are permanent at Knightsbridge barracks. The second regiment is on the same footing with the first, and of the same establishment. The average height of the men is 5 feet 11 $\frac{3}{4}$ inches; the horses are from 16 to 18 hands high, of a black colour, with long tails. In this regiment, as well as the other, there are five troops; each troop consisting of one captain, one lieutenant, one cornet, one quarter-master, three corporals, 49 privates, including a farrier, and one trumpeter. Each regiment has one kettle drummer. The officers usually ride bay-horses; the kettle drummers and trumpeters, grey. There are two "gold-sticks," one appertaining to each regiment: their duty is to attend alternately every month on his majesty. See *Life-GUARDS*.

A body of foot-guards was not regularly organized on the present plan till after the restoration. The regiment of general Monk, created duke of Albemarle, was, in compliment to him, retained on the establishment, when most of the other troops were disbanded. This regiment had been raised about ten years before the period alluded to, at Coldstream, in Scotland; and from this circumstance it assumed the name, which it has borne ever since. The year 1660 may thus be considered as the era of the formation of the foot-guards; and though other regiments were added, the Coldstream had the priority. The guards possess many peculiar honours and privileges: they have precedence of all others; their officers possess a higher rank in the army; and without expence to themselves, when on guard at St. James, they have a plentiful table kept for them by the public, and voted annually in the extraordinaries of the army. The king's person, the royal family, the Tower, and, in times of danger, the bank of England, are in a particular manner under their protection. Their uniforms are royal, with blue facings, and their pay superior to that of the marching regiments. See *Foot-GUARDS*.

The corps, denominated the royal regiment of horse-guards, blue, commonly called Oxford blues, derives its appellation from the noble family of Oxford, who was its first colonel in 1661. This regiment has distinguished itself

on a variety of occasions. The following circumstances are peculiar to this corps. It is the only regiment, denominated "horse," at present on the British establishment. The promotions, that of colonel excepted, are restricted to the regiment. The quarter-masters' commissions are signed by the king, so that they are properly termed commission-officers; whereas in all the other cavalry, or dragoon regiments, quarter-masters are only warrant-officers. The average height of the men is 5 feet 10 $\frac{1}{2}$ inches. The uniform of the officers is blue, faced with scarlet, gold lace, and buff lining; of the privates, blue, with plain red lappets, very broad buff cross-belts, and gloves of the same colour. The troopers' horses are black, with long tails. The corps consists of nine troops; and to each troop belong four commissioned officers, five non-commissioned officers, and 54 private men: there are, besides, the colonel, one lieutenant-colonel, one major, an adjutant, a regimental surgeon and assistant, and a veterinary surgeon. See *Horse-GUARDS*.

The establishment of a royal regiment of artillery took place early in the last century; the first commission of colonel having been issued, as it is said, in the first year of the reign of George II. In a short time, the number of companies was augmented from four to eight. The uniform was blue, turned up with red; and waistcoats and breeches of the colour of the facings were then worn by the officers. The artillery take the right of foot on all parades, and likewise of dragoons, when dismounted. Each battalion consists of one colonel commandant, one ditto en-second, one first lieutenant-colonel, two second lieutenant-colonels, one major, ten captains, ten captain-lieutenants, thirty lieutenants, one adjutant, one quarter-master, one surgeon, and one assistant surgeon. The establishment of each company is 120 rank and file. The standard height of the men is 5 feet 9 inches, and upwards. The uniform of the officers is blue, faced with scarlet, gold epaulettes, no lace, white waistcoat and breeches, boots, yellow breastplate on a white buff shoulder-belt. The uniform of the privates is blue, with red cuffs and collar, no facings, yellow lace, and buttons impressed with the ordnance arms. The sergeants wear frogged gold lace. The arms of the officers and sergeants are yellow-hilted swords; of the corporals, bombardiers, and privates, carbine and bayonet. The horse artillery have swords and pistols. The officers rise in a regular gradation by seniority. See *ARTILLERY*.

The first or royal regiment of foot claims a high degree of antiquity. It is undoubtedly the oldest regiment in the service. It is said to have been the body-guard of the Scottish kings, whence it has derived its name of the royal Scots, and to have been put upon the English establishment in 1633. The first colonel was nominated during the reign of Charles I.; but on the fatal issue of the civil wars to that monarch, this corps seems to have been disbanded. At the restoration of Charles II., this regiment was re-established. It consists of two battalions, both commanded by the same colonel: in every other respect they are considered as separate corps. The uniform of the officers is scarlet, faced with blue, gold lace embroidered; that of the private soldiers red, faced with blue and white lace.

The second, or queen's royal regiment of foot, was raised in the year 1661. The regiment being royal, the facings for the whole are blue; the lace for the privates white, with a blue stripe.

The third regiment of foot, called the "Buffs," was put upon the regular establishment of the army in the year 1665. It was denominated the "Buffs," from being the first whose accoutrements were made of leather prepared from the buffalo, after the manner of shamois. The waistcoats, breeches,

REGIMENT.

and facings of the coat, were afterwards directed to be made of a corresponding colour. When other regiments assumed this part of their appointment, the third acquired the name of the "Old Buffs." This regiment has the exclusive privilege of marching through the city of London by beat of drum. Its uniform is red, with buff facings; buff waistcoats and breeches. The 31st regiment, which has the same uniform, is commonly called the "Young Buffs."

The fourth, or king's own regiment of foot, was raised in the year 1680, by Thomas earl of Plymouth. This regiment was the first that joined king William, on his landing at Torbay; on which occasion his majesty honoured it with the title of the king's own regiment; and directed it to bear in its colours the lion of England, which still continues the badge of the regiment, and is worn on the breast-plate, buttons, cap, and pouch. The uniform of the regiment, at the beginning of the last century, was red, faced with blue velvet, and large velvet cuffs, richly embroidered with gold. The present uniform is red, with plain blue facings, silver buttons and epaulet, white waistcoat and breeches. On the epaulet, buttons, and breast-plate, are the crown and garter, and round the latter "The King's own Infantry." In the centre is the lion of England, and under it the number IV in small Roman figures.

The fifth regiment of foot was raised by James II.; but it followed the fortunes of the prince of Orange. When the 4th, 5th, and 6th regiments were first raised, they were not placed upon the British establishment, but sent by James II. for the service of the states-general. On the abdication of that monarch, and the subsequent election of William, prince of Orange, they were numbered and taken into the line, according to the periods at which they landed from Holland. Thus the 4th, which had originally been raised after the 5th, arrived in England before it, and took precedence. The 6th, which had been levied before the 5th, returned at a later period than either, and was consequently placed according to that date. The 5th regiment has been augmented to two battalions, by drafts from the militia; its uniform goshing green facings. The 24th, 54th, and 69th regiments are also faced with light green.

The sixth regiment of foot derives its origin from the seven years' war, in the course of which the United Provinces of Holland threw off their subjection to Spain. Its regular establishment did not take place until the year 1673; but it had previously served under the three first princes of Orange. This was one of the three regiments intended, on their formation, to serve in Holland; and, therefore, it was paid by the Dutch republic. It came over to this country with king William, at the revolution in 1688, and was incorporated in our military establishment, being numbered as the 6th in the British line. Its uniform is deep yellow facings, white lace, with yellow and red stripes. The 9th, 10th, 12th, 13th, 15th, 16th, 20th, 25th, 26th, 28th, 29th, 30th, 34th, 35th, 37th, 38th, 44th, 46th, 57th, 62d, and 67th regiments have also yellow facings and white lace; and are distinguished from each other by the variations of the stripes, the tinge of the colour, &c.

The seventh regiment of foot, or "Royal Fusileers," was raised, with nine others of infantry, and eight of cavalry, under James II., in the year 1685, three years before his abdication. As a fusileer regiment, the men wear caps, similar to those of the grenadiers, but somewhat shorter. In all other respects they are dressed and appointed as the soldiery of other battalions. Three years after this, another regiment was raised, under the denomination of "Royal Welsh Fusileers." This partiality for cap regiments is said to have been caused by the celebrity of the British grena-

diers, who were easily distinguished by their caps. (By a regulation in 1800, all the regiments of the line, as well as the guards, are to wear a kind of caps.) The officers in these regiments never carried spontoons, as the others did, till the late change, but had fusils, like the officers of the flank companies throughout the army. The other regiments of fusileers have second lieutenants, instead of ensigns. This regiment is peculiar in having none but first lieutenants, under the field-officers and captains. The uniform is royal, blue facings, with white lace, and a blue stripe. The 8th, 18th, 21st, 23d, 42d, and 60th regiments have also blue or royal facings, but different lace.

The first, or king's regiment of dragoon-guards, was raised and entered on the establishment on the 6th of June 1685. The establishment of this regiment, called, during its services in Germany in the course of the seven years' war, "Bland's dragoons," from the name of the officer who was then at the head of it, is ten troops, each consisting of one captain, one lieutenant, one cornet, one quarter-master, four serjeants, four corporals, one trumpeter, and seventy-one rank and file. The average height of the men is 5 feet 10 inches; of the horses, 15 hands 1½ inch. The uniform of the officers is scarlet and gold lace, blue cuffs and collar; no facings on the ordinary uniform. The uniform of the troopers, red jacket, faced half-lappet, blue, white lace, buttons marked K. D. G. The serjeants wear gold lace. The second, or queen's dragoon-guards, is one of the eight cavalry regiments raised in 1685, the second year after the accession of king James II. to the throne. Five of these remain on the English establishment, and three on the Irish: of the former five, three are distinguished as "Dragoon-guards," the other two as "Dragoons;" the first of which is denominated "the king's own regiment." The uniform of the officers red, faced with black velvet and silver lace; and that of the troopers red jacket, black collar and cuffs, royal lace, white buttons, marked Q. D. G. The serjeants wear silver lace. The third, or prince of Wales's dragoon-guards, is the last of the three regiments distinguished as dragoon-guards upon the British establishment. The uniform is scarlet, faced with white, and yellow buttons. The fourth, or royal Irish regiment of dragoon-guards, was raised, with seven others of the cavalry, in the year 1685, soon after James II. ascended the throne. It was originally called "the Prince of Wales's," or first regiment of horse; and, with the other three of horse upon the same establishment, it was, in the year 1788, put upon a new one, and called "Dragoon-guards," numbering on to seven; so that the fourth of horse, formerly so called, is now the seventh dragoon-guards. The uniform is royal, with silver lace. The fifth regiment of dragoon-guards, commonly called the "Green Horse," was originally the second of horse, and raised in England in the reign of king James II., in the month of July 1685. It was at that time put upon the regular British establishment. It went over with king William to Ireland in 1689, and remained more than 100 years upon the Irish establishment. It is now on the English establishment; and consists of nine troops, of the same strength with those of the fourth regiment of dragoon-guards; each troop consisting of one quarter-master, four serjeants, four corporals, one trumpeter, and seventy-one privates. The uniform of the regiment is green facings with gold lace for the officers, and yellow for the private men. The height of these men is in general from 5 feet 8 inches to 6 feet. The first, or royal regiment of dragoons, was raised for the service of Charles II. in 1683. Their badge is a horse-shoe, inclosing 1st D., encircled with a wreath of laurels; the regiment consists of nine troops, of the usual number. The colour of the horses is black. The

second, or royal North British dragoons, called the "Scots Greys," were raised in Scotland during the reign of James II. The uniform is red, with gold lace, no facings, but blue collar and cuff. The horses are of an iron-grey colour, except those of the officers and trumpeters, which are of a light grey, approaching to white. The fifth, or royal Irish regiment of dragoons, was raised in or about the year 1688. In consequence of the good behaviour of this regiment at the battle of Hochstet, in August 1704, three additional troops were put upon the establishment, making its strength to consist of nine troops. Again this regiment, assisted by the Scots greys, distinguished itself at the battle of Ramillies in 1706; and both corps were distinguished from other cavalry regiments, by being permitted to wear grenadier caps. The permanency of the nine troops was secured by an order, dated in 1798. At this time there was an insurrection of the rebels in the disaffected parts of Ireland, and this regiment was ordered to resist and suppress it. In order to supply the loss it sustained in several conflicts with the rebels, its officers were instructed to receive eligible recruits. Many were enlisted, who, as the event afterwards proved, were rebel-partisans, who entered into a desperate plot for seizing the garrison at Lehaunstoun and massacring every officer and loyal soldier. The conspirators were seized, and suffered according to their deserts. The regiment, however, had the mortification to find it announced in the public papers, that several privates belonging to the fifth or royal Irish dragoons, had been found guilty by a general court-martial of joining the rebels. In consequence of this the regiment was, on the 10th of April following, disbanded by an order from his majesty, dated April 8th, 1799. See Grose's Mil. Ant. vol. ii. appendix.

REGIMENTAL Court-martial. See COURT-Martial.
REGIMENTAL Staff. See STAFF.

REGIMENTALS, the uniform clothing of the army, consisting of a hat, coat, waistcoat, breeches, shirts, stocks, shoes, stockings, spats, spatterdashies, &c.

REGINA, in *Geography*, a town of Naples, in Calabria Citra; 12 miles N. of Cosenza.

REGINA *Aurarus*, in *Ornithology*, a name given by Nieremberg to a bird called by the Mexicans *cozcacoauhli*. It has obtained its name from its being able to fly against the strongest winds. It is of the bigness of an eagle, and its whole body is of a blackish purple, variegated with a brownish-yellow and deep black; its wings are variegated with black, yellow, and grey; its legs are red; its claws very strong and sharp; and its beak like that of a parrot; it has some rugose skin on the forehead, and about the beak; and its tail is black above, and grey underneath. It feeds on snakes, rats, and other vermin, but will also eat human dung; it flies very high; it is a native of Mexico, and breeds in spring; its feathers are said to be a remedy for many diseases; but the truth of this account is much to be doubted. Ray.

REGINA, *Salve*. See SALVE.

REGINELLI, NICOLA, in *Biography*, an Italian opera singer, renowned for his knowledge and the purity of his taste. He arrived in London in the autumn of 1746, an old but great singer, whose voice as well as person were in ruin. He first appeared on our stage in a pasticcio, called "Annibale in Capua." This performer was now turned of fifty; his voice a *soprano*, but cracked, and in total decay; his figure tall, raw-boned, and gawky; but there were fine remains of an excellent school in his taste and manner of singing; indeed, he had some refinements in his embellishments and expression, that cannot be described, and which we have not since heard in any other singer. In a *cantabile*, his taste, to

those who had places near enough to hear his *riffioramenti*, was exquisite; but the imperfections of his voice and figure disgusted those at a distance, to whose ears only the worst part of his performance arrived.

REGINO, a celebrated German ecclesiastical writer and chronicler, who flourished in the ninth and tenth centuries. He embraced the monastic life at the Benedictine abbey of Prum, in the diocese of Treves, and by his conduct gained such general respect among the fraternity, that in the year 892 he was made abbot, which office, however, from the jealousy of his rivals, he was obliged to resign in 899. After this he probably retired and spent the remainder of his days in the abbey of St. Maximin at Treves. He died about the year 908. He was author of "A Chronicon," extending from the birth of Christ to the year 907, which is said to be very useful in illustrating the history of his time, and particularly that of the Franks and Germans. This chronicon was published at Frankfort in 1583, with an appendix by another hand, continuing it from the year 907 to 972, and it is to be found in Pistorius's collection, entitled, "Scriptores de Rebus Germanicis." Regino was author likewise of "De Disciplinis Ecclesiasticis et Religione Christiana," in two books, of which the first contains those canons which relate to ecclesiastical persons, and the second, those which regard the laity. This work was undertaken by him about the year 906, at the desire of the archbishop of Treves, for the special benefit of his diocese. It was first published, with an appendix, by Joachin Hildebrand, at Helmstadt, in 1659, from a manuscript of Flacius Illyricus; and afterwards by M. Baluse, with additions, and a learned preface and notes, in 1671. Trithemius pronounces Regino to have been the best German writer of his age.

REGINO, in *Geography*, a town of Golo, or the island of Corsica, in the department of Calvi; the canton of which contains 3913 inhabitants.

REGIO ASSENSU, in *Law*, is a writ by which the king gives his royal assent to the election of a bishop.

REGIONMONTANUS, in *Biography*. See MULLER.

REGION, in *Anatomy*, denotes a division of the human body. Some anatomists have divided the body into three regions, or venters.

The upper region is that of the head, reaching as low as the first vertebra, and comprehending the animal organs, the brain, &c. See HEAD, &c.

The middle region is that of the thorax or breast, which Hippocrates calls the upper venter, and which reaches from the clavicles to the diaphragm: in this are contained the vital parts, as the heart, lungs, &c. See HEART, LUNGS, &c.

The third, or lower region, is the abdomen or belly, &c. containing the natural parts, destined for digestion, purgation, and generation. See ABDOMEN.

REGION, *epicolic*, *epigastric*, and *umbilical*. See the adjectives.

REGION, *Regio*, in *Geography*, a country, or particular division of the earth; or a tract of land inhabited by people of the same nation.

The modern astrologers divide the moon into several regions, or provinces, to each of which they give its proper name. See MOON.

REGION, in *Physiology*. Authors divide the atmosphere into three stages, called the *upper*, *middle*, and *lower* regions. See ATMOSPHERE.

The lowest region is that in which we breathe, and is bounded by the reflexion of the sun's rays, that is, by the height to which they rebound from the earth.

The middle region is that in which the clouds reside, where
meteors

meteors are formed, &c. extending from the extremity of the lowest to the tops of the highest mountains.

The upper region commences from the tops of the mountains, and reaches to the utmost limits of the atmosphere. In this reigns a perpetual, equable calmness, clearness, and serenity.

REGION, *Elementary*. See ELEMENTARY.

REGION, *Ethereal*, is used for the whole extent of the universe, including the orb of the fixed stars, &c.

REGIONS of the Sea. As some naturalists, in their descriptions of the subterraneous parts of the globe, distinguish the earth into three regions of different depths, in which different temperatures are observed; so in describing the sea, they allow it two regions; the one extending from the surface of the water, down so low as the rays of the sun can pierce, and extend their influence; and the other, from the lowest bounds of that to the bottom. It is easy to see that these regions rather regard quality than space, and that their boundaries are far from being regular, or equal in all places, and at all times. The places exposed to the hottest sunshine will have the largest upper region; those where the sun has least power will have the smallest; and the same part of the sea will have its upper region more or less deep, according to the season of the year. This upper region of the sea is always more or less hot; the lower region, except in some few particular places, is every where cold; and the water, where the upper region is large, is always remarkably still and quiet in the lower. Boyle of Cosmical Qualities.

REGION, *Subterranean*. The earth is not only divided on its surface into regions and countries, but philosophers, who have had occasion to discourse of its inner parts, have also divided them into three distinct regions, according to their different depths from the surface. The temperature of the subterranean parts of the globe is distinguished according to the division of these regions, but is not so regular and precise as some have supposed. The first region of the earth is very variable, both as to bounds and temperature. The second region seems for the most part cold, in comparison of the other two; but in several places, which, by reason of their distance from the surface of the earth, it would be natural to call the middle region, the temperature of the air is very different at the same seasons of the year, which shews that it depends on something more than bare depth from the surface. The third region of the earth is universally observed to be warm, but by no means regularly or uniformly: the same depth in some places, giving only a moderate warmth, while in others it gives a very considerable heat.

Borrichius tells us of a certain abbé, fond of chemistry, and particularly curious in the matter of long digestions by regular heat, who found a way of making a furnace perpetually warm, by piercing the earth to a certain depth, and using the heat of this third region of it. His method, we are told, was to bore a hole with a pike twenty feet deep, and pour into it ten or twelve pounds of quicksilver; this made its way into the strata, and through them in a body into the chambers of heat in this third region, where the heat, having a vent upwards, made by this opening, never failed to ascend in a perpetual and regular stream, and gave that regular and digesting heat that no artificial fire could equal. But this is an alchemical story. Boyle of Cosmical Qualities. Borrich. de Ortu Chem.

REGION, in ancient Rome, a part or division of the city. Romulus divided his little city into three tribes, and Servius Tullius added a fourth; which division continued till Augustus's time, who first divided the city into fourteen regions, over each of which he settled two surveyors, called *curatores viarum*, who were made annually, and took their

divisions by lot. These fourteen regions contained 424 streets, 31 of which were called great or royal streets, which begun at the gilt pillar that stood at the entry into the open place in the middle of the city.

The extent of these divisions varied greatly, some being from 12,000 or 13,000 to 33,000 feet and upwards in circumference. Authors, however, are not agreed as to the exact limits of each.

According to Kennet, who formed his division on the authority of the accurate Panvinus, the different regions were as follow: The *first* region, called "Porta Capena," contained 9 streets, 3 luci, or consecrated groves, 4 temples, 6 ædes, or sacred buildings, 6 public baths, 4 arches, 14 granaries, 12 mills for grinding corn, and 121 domi, or great houses. The whole compass of this region, or ward, was 13,223 feet. The *second* region, denominated "Cælimontium," included 12 streets, 2 luci, 5 temples, the public baths of the city, 80 private baths, the great shambles, 23 granaries, 23 mills, and 133 great houses. Its compass was 13,200 feet. The *third* region, or Isis and Serapis, contained 8 streets, 2 temples, the amphitheatre of Vespasian, the baths of Titus, Trajan, and Philip, 19, or, as some say, 29 granaries, 23 mills, 160 great houses. Its compass was 12,450 feet. The *fourth* region, Via Sacra, or Templum Pacis, comprehended 8 streets, 10 temples, the colossus of the sun, 120 feet high, the arches of Titus, Severus, and Constantine, 75 private baths, 18 granaries, 24 mills, and 138 great houses. Its compass, according to some, was only 8000, but, according to others, 14,000 feet. The *fifth* region, or Esquilina, included 15 streets, 8 luci, 6 temples, 5 ædes, 75 public baths, 18 granaries, 22 mills, and 180 great houses. Its compass was 15,950 feet. The *sixth* region, Aeta Semita, contained 12 or 13 streets, 15 temples, 2 porticos, 2 circi, 2 fora, 75 private baths, 19 granaries, 23 mills, 155 great houses. Its compass was 15,600 feet. The *seventh* region, Via lata, included 40 streets, 4 temples, 75 private baths, 3 arches, 17 mills, 25 granaries, and 120 great houses. Its compass was 23,700 feet. The *eighth* region, Forum Romanum, included 12 streets, 21 temples, 66 private baths, 10 ædes, 9 porticos, 4 arches, 7 fora, 4 curiæ, 7 basilicæ, 6 columns, 18 granaries, 30 mills, and 150 great houses. Its compass was 14,876 feet. The *ninth* region, Circus Flaminius, comprehended 20 streets, 8 temples, 20 ædes, 12 porticos, 2 circi, 4 theatres, 3 basilicæ, 2 curiæ, 5 baths, 2 arches, 2 columns, 32 mills, 32 granaries, and 189 great houses. Its compass was 30,560 feet. The *tenth* region, Palatium, contained 7 streets, 10 temples, 9 ædes, 1 theatre, 4 curiæ, 15 private baths, 12 mills, 16 granaries, and 109 great houses. Its compass was 11,600 feet. The *eleventh* region, Circus Maximus, included 8 streets, 22 ædes, 15 private baths, 16 granaries, 12 mills, and 189 great houses. Its compass was 11,600 feet. The *twelfth* region, Piscina Publica, contained 12 streets, 2 ædes, 68 private baths, 28 granaries, 25 mills, and 128 great houses. Its compass was 12,000 feet. The *thirteenth* region, or Aventinus, included 17 streets, 6 luci, 6 temples, 74 private baths, 36 granaries, 30 mills, and 155 great houses. Its compass was 16,300 feet. The *fourteenth* region, Transtiberina, contained 23 streets, 6 ædes, 136 private baths, 20 granaries, 32 mills, and 150 great houses. Its compass was 33,409 feet.

REGIONARY, REGIONARIUS, in *Ecclesiastical History*, a title given, from the fifth century, to persons who had the charge and administration of the church affairs within a certain district or region.

At Rome there were anciently seven regionary deacons, who

who presided over a kind of hospitals, and looked to the distribution of alms.

There were also regionary subdeacons, and regionary notaries, as also regionary bishops, &c.

A regionary bishop was properly a missionary invested with an episcopal character, but without being attached to any particular see, that he might be at liberty to go to preach, and perform other functions of his ministry, whithersoever the Spirit of God and the wants of the people should call him.

REGIS, PETER-SYLVAN, in *Biography*, a celebrated French philosopher, was born at Salvat de Blanquefort, in the Agenois, in the year 1632. After having been instructed in classical learning and the belles lettres, by the Jesuits, at Cahors, he entered himself a student of divinity at the university of that city, intending to qualify himself for the clerical profession. This, however, he abandoned, in order to devote himself to the study of the Cartesian philosophy, which at that time was taught with great success by Rohault. With this view he went to Toulouse in 1605, and read a course of lectures upon the principles of Descartes, and was attended by persons of all ranks and characters, who inlisted themselves in the number of his disciples. Among these were to be found the magistrates, clergy, and even the women of Toulouse, who affected to be the zealous converts to the new philosophy, in opposition to the old. To express their gratitude to the man who had been the instrument of diffusing this light over their city, the inhabitants granted him a pension; a circumstance which, it has been observed, corresponded more with the spirit and usages of ancient Greece, than of modern times. In 1680 he came to Paris, considering that as the most proper scene for the exhibition of his talents. Here he was extremely popular, and the friends to the Aristotelian system began to be alarmed at his success, and complained against him to the archbishop of Paris, who prohibited him from continuing his lectures, and they were accordingly suspended. But after a short time, the prelate withdrew his interdiction, and Regis devoted the remainder of his life to the propagation of the Cartesian philosophy, as well by his writings as his lectures. In 1699 he was admitted a member of the Academy of Sciences, but his infirmities prevented him from attending its meetings. He died in the year 1707, at the age of 75, highly esteemed by persons of the first distinction for talents and rank. He was author of a great number of works, of which the following may be mentioned: "A System of Philosophy, containing Logic, Metaphysics, and Morals;" "An Answer to the Book of M. Huet, entitled 'Censura Philosophiæ Cartesianæ,'" which is mentioned by Bayle as a model for every writer on the same side of the question; "An Answer to the Critical Reflections of Du Hamel on the System of Philosophy."

REGIS, in *Geography*, a town of Saxony, in the bishopric of Nuremberg; 14 miles S. of Leipzig.

REGIS, *St.*, a village of Upper Canada, on the St. Lawrence, half a mile N. from the N. line of the United States. It is seated on a beautiful elevated plain, in the angle between the mouth of St. Regis river and the St. Lawrence. It consists of about 80 houses of hewn logs, inhabited by about 100 Indian families, of the Caghnowaya tribe, who have lived here more than half a century. They are peaceable, honest, and industrious. Their diversions are foot-races, playing at ball, and dancing. They are Roman Catholics, and have a handsome stone church, with a spire, and generally a minister. These Indians have 30,000 acres of land reserved to them S. of the village. They keep a great number of horses and cattle, and raise plenty of corn

on the fertile islands in St. Lawrence. From St. Regis there is a good road to Plattsburg, on Champlain; the distance being 72 miles.—Also, a river of Canada, which rises from lakes near Racket river, and enters the St. Lawrence at the village above-mentioned.

REGIS *Pondus*. See PONDUS.

REGIS *Villa*. See VILLA.

REGISTAN, or *Sandy Desert of Agimere*, in *Geography*, a sandy desert, forming the western boundary of Hindoostan, between the country of Agimere and the Indus. The northern extreme of this desert bounds the dominions of the Seiks on the south.

REGISTER, REGISTRUM, a public book serving to enter and record memoirs, acts, and minutes, to be had recourse to occasionally, for the justifying of matters of fact.

Menage derives the word, by corruption, from *regeſum*, a book containing extracts of several books, &c. collected together: "Dicitur regeſum quasi iterum gestum." Others derive it from the old French *gister*, to lie down in a bed, &c.

The law of Scotland is rendered very easy and regular, by means of the great number of registers, for recording the conveyances of lands, &c. of private persons. Of these there are two kinds: the one general, fixed at Edinburgh, under the direction of the lord register, who, before the Union, was the fifth officer of the state, and, besides the registry, was clerk of the parliament, treasury, exchequer, and session.

The other is particularly kept in the several shires, stewartries, and regalties. The clerks of it are obliged to transmit the registers of their respective courts to the general register; and the notaries their protocols: and here they are so disposed, that, on demand, the lieges can have a view of any writs which the law requires to be registered, or which parties, for their security, have thought fit to record.

The registers were first set on foot by act of parliament, under king James VI., to the unspeakable advantage of the subject.

No man can have a right to any estate, but it must be registered within forty days of his becoming seized of it, otherwise it is null; and by this means all secret conveyances are cut off.

By a law in 1704, it was enacted, that a memorial of all deeds and conveyances, and of all wills and devises in writing, by which any honours, manors, &c. in the West Riding of Yorkshire, might be any way affected in law or equity, may, at the election of the party or parties concerned, be registered: and that, after such register, every subsequent deed or conveyance of the said honours, manors, &c. so registered, or any part of it, shall be adjudged fraudulent and void, unless a memorial of it shall be also registered: and the like of wills, &c. But this act did not extend to copyhold estates, nor to leases at rack-rent, nor to any lease not exceeding twenty-one years.

In the year 1708, a similar statute was passed for the registering of deeds, conveyances, wills, devises, mortgages, &c. in the East Riding of Yorkshire: and all the provisions and clauses in this act were hereby extended to the honours, manors, lands, and tenements, in the West Riding of the same county.

In 1709, a law was made for the public registering of deeds, conveyances, wills, &c. in the county of Middlesex; which may be done for the fee of one shilling: and every deed or conveyance, which shall hereafter be executed, shall be adjudged fraudulent and void, against any subsequent purchaser or mortgagee for valuable consideration, unless such memorial of it be registered according to the direction

of this act, before the registering of the memorial of the deed or conveyance, under which such subsequent purchaser or mortgagee shall claim; and the like as to memorials of wills not registered.

In 1735, a similar register of mortgages, &c. was legally enacted for the North Riding of the county of York; whence York and Middlesex are register counties. (2 & 3 Ann. cap. 4. 6 Ann. cap. 35. 7 Ann. cap. 20. 8 Geo. II. cap. 6.) These statutes do not extend to copyhold estates, leases at a rack-rent, or to any leases not exceeding 21 years, where the possession goes with the lease; nor to any chambers in the inns of court.

Many have wished that the same regulation was extended to all the counties of England and Wales; but judge Blackstone observes, that, however plausible these provisions may appear in theory, it hath been doubted, by very competent judges, whether more disputes have not arisen in those counties, by the inattention and omission of parties, than prevented by the use of registers.

REGISTER, more correctly *Registrer*, *Registrarius*, is also used for the clerk, or keeper of a register, or registry.

Of these we have several, denominated from the registers they keep; as register of the high court of delegates, registers of the arches court of Canterbury, register of the court of admiralty, register of the prerogative court, registers of the province of Canterbury, register of the archdeaconry of Middlesex, &c. register of the faculty office, and register of the garter, who is always dean of Windsor, and deputy registers.

There are also, in the court of chancery, the principal register, the lord chancellor's registers, the registers of the master of the rolls, entering registers, and register of the affidavits.

The appellation of register or registrarius is also given to a notary. See NOTARY, and NOTARY, *Public*.

REGISTER, *City*. See TOWN-*Clerk*.

REGISTER of a parish church, is a book in which the yearly baptisms, marriages, and burials, of each parish, are orderly registered. See MARRIAGE.

This practice was laudably instituted by that great but unfortunate person Thomas Cromwell, earl of Essex, anno 1538, while he was vicar-general to king Henry VIII.; and it was continued in the reigns of king Edward VI. and of queen Elizabeth.

These parish registers are to be kept in a coffer, provided by the churchwardens, with three locks and keys, one of which is to remain with the minister, and the other two with the churchwardens severally, so that neither the minister without the two churchwardens, nor the churchwardens without the minister, shall at any time take that book out of the said coffer. These parish registers are to be subscribed by the minister and churchwardens; and the names of the persons shall be transmitted yearly to the bishop; and it has been enforced by canon 70, and by statute, &c.

By 26 Geo. II. c. 33. to make a false entry in a marriage register, to alter it when made, to forge or counterfeit such entry or a marriage licence, or aid and abet such forgery, or to utter the same as true knowing it to be counterfeit, or to destroy or procure the destruction of any register, in order to vacate any marriage, or subject any person to the penalties of this act; all these offences, knowingly and wilfully committed, subject the party to the guilt of felony, without benefit of clergy.

By the 30 C. II. c. 5. for burying in woollen, it is enacted, that the minister of every parish shall keep a register in a book to be provided at the charge of the parish,

and make a true entry of all burials within his parish, and of all affidavits of persons being buried in woollen brought unto him according to the said act; and where no such affidavit shall be brought to him within the time therein limited, he shall enter a memorial thereof in the said registry, against the name of the party interred, and of the time when he notified the same to the churchwardens or overseers of the poor according to the said act.

An approved register of births, consisting of certificates signed by two persons who were present at the said births, and entered in a book signed by the register or secretary, is kept with great accuracy, and authenticated by a committee, for the benefit of Protestant dissenters and others. This book is deposited and carefully preserved at Dr. Williams's library, Red-cross Street, Cripplegate, to which any person may have free access at the stated hours, under the direction of the secretary of the said library, whose attention to his office entitles him to public respect.

REGISTER is also a title of a book, containing the forms of most of the writs, original and judicial, used in common law. This is called the *register of writs*, or *registrum omnium brevium*. This register, Coke on Littleton observes, is one of the most ancient books of the common law. And judge Blackstone observes concerning it, that it is the most ancient and highly venerable collection of legal forms, upon which Fitzherbert's *Natura Brevium* is a comment, and in which every man, who is injured, will be sure to find a method of relief, exactly adapted to his own case, described in the compass of a few lines, and yet without the omission of any material circumstance.

REGISTER, in *Antiquity*, a book or table at Athens, belonging to each particular *φρατρία*, or ward, in which all fathers were obliged to enrol their sons, making oath, at the same time, that every son, so registered, was either born to them in lawful wedlock, or lawfully adopted. The adopted sons were registered in the festival Thargelia; the natural, upon the third day of the festival Apaturia.

At what age children were thus registered is not agreed. Some are of opinion, that at every return of the Apaturia it was customary to register all the children that had been born that year. Others affirm, that they were commonly three or four years old before they were registered.

There were two other seasons when young Athenians were enrolled in a public register: one, when they arrived at the age of eighteen years, and were admitted into the number of the *εφηβοί*, and was performed on the third day of the festival Apaturia; and the other, before the festival Panathenæa, when those who were twenty years old were entered in a register, called *λαξιαρχικόν γραμματεῖον*, in which the names of all persons of that borough, who were of age to succeed in the *λαξίς*, or inheritance of their fathers, were entered. This was termed *to be registered among the men*: and the persons, thus enrolled, became their own masters, and free from the government of their guardians. Potter's *Arch. Græc.* vol. i. p. 48.

REGISTERS of *Estates*, the accounts of particular things which belong to them, as those of rentals, valuations of fields, names, admeasurements, different portions of land, cottages, and other buildings distinct from the farms, and any other separate parts. In these registers the valuations are to be inserted in columns, as they arise from surveys or other ways, and afford the means of fixing the real values in re-letting the lands or for other purposes.

Also, a general register of the *timber trees* which are growing on the several divisions of the estates, should always be kept; in which the number contained in each separate wood, grove, hedge-row, or any other part, must be entered,

tered, with their kinds, and the admeasurement of each, for the use of the proprietor and wood managers.

A great many other sorts of particulars regarding the estates may likewise be usefully and conveniently put down in these registers.

REGISTER of *Seamen*. See *MANNING the Fleet*.

REGISTER *Ships*, or *Ships of Register*, in *Commerce*, were vessels to which the king of Spain, or the council of the Indies, granted permission to go and traffic in the ports of Spanish America.

They were thus called, because the ships were to be registered before they set sail from Cadiz, which was the place where they usually loaded for Buevos Ayres.

These vessels, by the tenor of the cedula or permit, were not to exceed three hundred tons; but there subsisted that good understanding between the merchants and the council of the Indies, that ships of five or six hundred tons frequently passed unnoted.

These register ships, which were first introduced in order to furnish America with a regular and timely supply, and thus to prevent a contraband trade with the English, French, and Dutch islands, were fitted out, during the intervals between the stated seasons, when the galleons and flota sailed, by merchants in Seville or Cadiz, upon obtaining a licence from the council of the Indies, for which they paid a very high premium, and were destined for those ports where any extraordinary demand was foreseen or expected. In proportion as experience manifested the advantages of carrying on trade in this mode, the number of register ships increased, and at length, in the year 1748, the galleons, after having been employed upwards of two centuries, were finally laid aside. From that period there has been no intercourse with Chili and Peru, but by single ships dispatched from time to time, as occasion requires, and when the merchants expect a market will open. These sail round Cape Horn, and convey directly to the ports in the South sea the productions and manufactures of Europe, for which the people settled in those countries were formerly obliged to repair to Porto Bello or Panama.

But as all the register ships destined for the South seas were obliged to take their departure from Cadiz, and were under a necessity of returning thither, this branch of the American commerce, even in its new and improved form, continued subject to the restraints of a species of monopoly, and felt its pernicious effects.

The intercourse between Spain and her colonies has in later times been much improved and facilitated. In the year 1764, Charles III. appointed packet-boats to be dispatched on the first day of each month from Corunna to the Havanna or Porto Rico. From thence letters are conveyed in smaller vessels to Vera Cruz and Porto Bello, and transmitted by post through the kingdom of Tierra Firme, Granada, Peru, and New Spain. Packet-boats also sail with the same regularity, once in two months, to Rio de la Plata, for the accommodation of the provinces to the east of the Andes.

With this new arrangement for facilitating intercourse a scheme of extending commerce has been more immediately connected. Each of the packet-boats, which are vessels of some considerable burdén, is allowed to take in a loading of such commodities as are the product of Spain, and most in demand in the ports whither they are bound. In return for these, they may bring home to Corunna an equal quantity of American productions. This regulation may be considered as the first relaxation of those rigid laws, which confined the trade with the new world to a single port, and the first attempt to admit the rest of the kingdom to

some share in it. This measure of relaxation was soon followed by another more decisive. In the year 1765, Charles III. laid open the trade to the windward islands, Cuba, Hispaniola, Porto Rico, Margarita, and Trinidad, to his subjects in every province of Spain. This ample privilege was soon after extended to Louisiana, and to the provinces of Yucatan and Campeachy. As soon as this general liberty was permitted, it produced the most beneficial effects: and it has been computed, that such a number of ships was soon employed in the free trade, that the tonnage of them far exceeded that of the galleons and flota, at the most flourishing era of their commerce. This arrangement extended its good effects through every province of the kingdom; and by opening a new market for their various productions and manufactures, encouraged and added avidity to the industry of the farmer and artificer. Spain has also permitted a free trade between the colonies themselves. In the year 1774 Charles III. published an edict, granting to Peru, New Spain, Guatimala, and Granada, the privilege of a free trade with each other. See Robertson's *Hist. of America*, vol. iii.

REGISTER, among *Letter Founders*, is one of the inner parts of the mould in which the printing types are cast. Its use is to direct the joining of them justly together again, after opening them to take out the new-cast letter.

REGISTER, in *Printing*, the disposing of the forms of the press, so as that the lines and pages printed on one side of the sheet meet exactly against those on the other; which is done by means of two points in the greater or outward tympan.

REGISTER, in *Organ-building*, is another word for a stop in that instrument; but is in fact only a lath pierced with holes, corresponding with those in the found-board, which by drawing out the stops opens the holes, and putting them in shuts them. By these sliders each stop speaks or is silent. Register is figuratively used by musicians in speaking of a voice, in which real and falset notes are not well united. Mr. Braham's *high* notes, for example, are said to be of a different register from the *low*.

REGISTERS, in *Chemistry*, are holes, or chinks, with stopples to them, contrived in the sides of furnaces, to regulate the fire; *i. e.* to make the heat immediately more intense, or remiss, by opening them to let in the air, or keeping them close to exclude it. See *FIRE-places* and *FURNACE*.

REGISTRY, REGISTRUM, comprehends the office, books, and rolls, in which the proceedings of chancery, or any spiritual court, are registered or recorded.

REGISTRY of *Shipping*, in *Commerce*. The registering of ships appears to have been first introduced into this country by the *NAVIGATION Act*, 12 Car. II. c. 18. § 10. By this statute, however, foreign ships only, "British owned," were required to be registered. By stat. 7 & 8 W. III. c. 22. § 17, British or plantation built ships, British owned, if intended to be employed in the plantation trade, and also all "prize ships," were required to be registered; and in consequence of a regulation at the admiralty, ships for which Mediterranean passes were wanted, were also to be registered. The provisions in the acts requiring registry are founded upon the wisest policy, and are not less calculated to prevent the commission of private fraud upon individuals, than to advance the public policy of the state. By stat. 26 Geo. III. c. 60. (lord Hawkesbury's act), no ship or vessel foreign built (except such as have been condemned as lawful prize in any court of admiralty), nor any ships or vessels built or rebuilt upon any foreign made keel or bottom, although owned by British subjects, and navigated according

REGISTRY.

according to law, shall be entitled to the privileges of a British built ship, or of a ship owned by British subjects; and all the privileges and advantages allowed shall be confined to such ships only as are wholly of the built of Great Britain or Ireland, Guernsey, Jersey, and the Isle of Man, or some of the plantations in Asia, Africa, or America, now belonging, or which may hereafter belong to his majesty, except such foreign built vessels as before the 1st of May 1786 did truly and wholly belong to British subjects, navigated according to law, and duly registered, which shall continue to enjoy the privileges to which such ship or vessel is by law entitled; nor shall this act prevent any such vessel which may have been begun to be repaired or rebuilt before the 1st of May 1786 from being registered, provided it shall appear upon oath, to the satisfaction of the commissioners of the customs, that such vessel was stranded by the act of Providence, and was at the time of being so stranded the sole property of some foreigner, or a droit of the admiralty; and if it shall appear that such vessel, from the damage received, was rendered unfit to proceed to sea without undergoing a thorough repair in this kingdom, and that she was necessarily sold for the benefit of the foreign owners, or under an order or commission from the court of admiralty, and that she was fairly and openly purchased by a British subject, and being the sole and entire property of such British subject, that she had been so much repaired, that two-thirds of her at least are of British built, she may be registered. §. 1.

No vessel shall be deemed British built, or enjoy the privileges belonging to British built vessels, which shall be rebuilt or repaired in any foreign port, if such repairs shall exceed 15*s.* for every ton, unless such repairs shall be rendered necessary by extraordinary damage, and absolutely necessary to enable her to perform the voyage, and to return in safety to some place or port within his majesty's dominions; and before such vessel shall be so repaired, the master shall report her state, and condition upon oath to the British consul or other chief officer at the port where such repairs may be necessary, and cause the same to be surveyed by two persons to be approved of by such consul or chief British officer, and shall deliver to such consul or officer, in writing, the particulars of the damage sustained, and verify upon oath the particulars and amount of the repairs, and that the same were become necessary in consequence of damage sustained during her voyage, to enable the same vessel to prosecute her intended voyage, and to return to some port within his majesty's dominions, which must be certified under the hand and seal of the chief consul or other officer; or if no such consul, &c. shall be there resident, the survey shall be made by two persons to be approved of by two known British merchants residing at or near such port. And the master of such ship shall produce to such merchants vouchers of the particulars and amount of the repairs, and their certificate shall be of the same effect as that of the British consul or chief officer. And the masters of vessels repaired in any foreign port shall make oath before the collector and comptroller, or other principal officer of the customs in the first port of arrival (if required so to do), describing the nature and amount of such repairs; and if such expence shall exceed 15*s.* per ton, and the master or commander of such ship shall neglect or refuse to deliver to such collector or comptroller, or other principal officer of the customs, the certificate by this act required to be produced, such vessels shall to all intents and purposes be deemed foreign built. §. 2.

Ships above 15 tons British owned shall be registered in the manner hereinafter mentioned, and the persons claim-

ing property therein shall cause the same to be registered, and obtain a certificate of such registry from the collector or comptroller of the customs of Great Britain, or the Isle of Man, or from the governor, lieutenant-governor, or commander-in-chief and principal officer of the customs resident in the islands of Guernsey or Jersey, or in any of the said colonies, plantations, or islands respectively.

By § 4, no registry is to be made except in the port to which the vessel belongs.

The port to which any ship or vessel shall hereafter be deemed to belong, shall be the port from or to which the same shall usually trade, or being a new ship, shall intend so to trade, and at or near which the husband or acting owners usually reside.

No American vessel shall be entitled to be registered, or to any of the privileges of a British built ship or vessel, unless such ship shall have been taken and condemned as lawful prize, or having been stranded, shall have been built or rebuilt, and registered in the manner before practised and allowed. §. 7.

No registry shall be made or certificate granted until oath be taken and subscribed before the persons herein before authorized to make such registry and grant such certificate, by the owner of such ship or vessel, if the same belong to one person only; or, in case there shall be two joint-owners, then by both of them, if both be resident within 20 miles of the port where such registry required, or by one of such owners, if one or both be resident at a greater distance; or if the number of such owners shall exceed two, then by the greater number of them, if the greater number shall be resident within 20 miles of such port, not exceeding three of such owners, or by one of such owners, if all shall be resident at a greater distance. §. 9 and 10.

In case the owners shall amount to three or more, and three of such owners shall not personally attend to take and subscribe the oath directed, then such owner or owners as shall attend and take and subscribe the oath, shall further make oath that the part-owner or part-owners absent, is or are not resident within 20 miles, and hath or have not, to his or their knowledge or belief, wilfully absented himself or themselves to avoid taking the said oath, or is or are prevented by illness. §. 11.

By way of identifying the vessel to which a certificate of registry is alleged to be granted, the surveying officer shall go on board such ship or vessel as is to be registered, and strictly admeasure the same in the presence of the master, or any other person appointed for that purpose on the part of the owners, or by the said master, and shall deliver a true account in writing of all such particulars of the built, description, and admeasurement of such ship or vessel as are specified in the certificate, to the person authorized to make such registry; and the said master or such person as shall attend on the part of the owners, is to sign his name to the certificate of such surveying officer, provided such master or other person shall consent and agree to the several particulars set forth in the said certificate. §. 12.

Surveying officers making or granting false certificates to forfeit 100*l.*, and be for ever incapable of holding any office under his majesty. §. 13.

The tonnage of any vessel when afloat is to be ascertained by the following method, *viz.* drop a plumb line over the stern of the ship, and measure the distance between such line and the after part of the stern post at the load water mark; then measure from the top of the said plumb line, in a parallel direction with the water, to a perpendicular point immediately over the load water mark, at the fore part of the main stem: subtracting the above distance from such admeasure-

REGISTRY.

admeasurement, the remainder will be the ship's extreme length, from which are to be deducted three inches for every foot of the load draught of water for the rake abaft, and also three-fifths of the ship's breadth for the rake forward; the remainder shall be esteemed the just length of the keel to find the tonnage; and the breadth shall be taken from outside to outside of the plank in the broadest part of the ship, either above or below the main-wales, exclusive of all manner of sheathing or doubling, that may be wrought upon the side of the ship; then multiplying the length of the keel for tonnage by the breadth so taken, and that product by half the breadth, and dividing by 94, the quotient shall be deemed the true contents of the tonnage. Nothing in this act to be construed to alter the manner of admeasuring the tonnage of any ship which has heretofore been practised for the purpose of ascertaining the light duties, or any other duties or imposts payable according to the tonnage of any vessel. *f. 14.*

At the time of obtaining the certificate of registry, bonds shall be given to his majesty by the master, and such of the owners who shall attend, in the following penalties:

If a decked vessel, or from 15 to 50 tons, 100*l.*; 50 to 100 tons, 300*l.*; 100 to 200 tons, 500*l.*; 200 to 300 tons, 800*l.*; 300 and upwards, 1000*l.*

The condition of every bond given upon registry shall be, that such certificate shall not be sold, lent, or otherwise disposed of to any person or persons whomsoever, and that the same shall be solely used for the service of the ship or vessel for which it was granted; and that in case such vessel shall be taken by the enemy, burned or broken up, or otherwise prevented from returning to the port to which she belongs, the certificate, if preserved, shall be delivered up within one month after the arrival of the master in any port or place in his majesty's dominions, to the collector or comptroller of some port in Great Britain, or the Isle of Man, or of the British plantations, or to the governor, lieutenant-governor, or commander-in-chief for the time being, of the islands of Guernsey or Jersey; and that if any foreigner, or any person or persons for his use and benefit, shall purchase, or otherwise become entitled to the whole or any part or share of, or any interest in such vessel, and the same shall be within the limits of any port in Great Britain, Guernsey, Jersey, Man, or the British colonies, plantations, islands, or territories aforesaid, then in such case the certificate of registry shall, *within seven days after such purchase or transfer of property* in such ship or vessel, be delivered up to the person or persons authorized by this act to make registry and grant certificates thereof at such port and place respectively; and if such ship or vessel shall be in any foreign port when such purchase or transfer shall take place, then that the same shall be delivered up to the British consul or other chief British officer resident at or nearest to such foreign port; or if such vessel shall be at sea, at the time of such transfer of interest and property, then the said certificate of registry shall be delivered up to the British consul or other chief British officer at the foreign port or place in or at which the master or other person having or taking the command of such ship or vessel shall first arrive after such purchase or transfer of property at sea, immediately after his arrival at such foreign port; but if such master above-mentioned in the case above-mentioned shall not arrive at a foreign port, but shall arrive at some port of Great Britain, Guernsey, Jersey, Man, or his majesty's said colonies, plantations, islands, or territories, then the said certificate shall be delivered up in manner above-mentioned, within 14 days after the arrival of such ship or vessel, or of the person who had the command thereof, in any port of Guernsey,

Jersey, Man, or any of his majesty's said colonies, plantations, islands, or territories. And if any pass, called a Mediterranean pass, shall have been obtained and procured by any such ship or vessel, then and in such case the same shall be delivered up at the same time, and in like manner with the certificate of registry, to the persons hereinbefore authorized to receive such certificate of registry: and such certificates so delivered up, shall be transmitted forthwith to the commissioners of the customs in England and Scotland respectively; and such Mediterranean passes shall also be transmitted to the admiralty of Great Britain, by the person or persons authorized to receive such certificate and passes, that the same may be cancelled. *f. 15.*

In case of any alteration of property in the same port by the sale of any share or shares in any ship or vessel after registering thereof, such sale or transfer of property shall always be acknowledged by indorsement in the certificate of registry, before two witnesses, in order to prove that the entire property in such ship is vested in some of the subjects of Great Britain. In case any dispute should arise concerning the same, the above indorsement to be signed by the person transferring the property in such ship or vessel, or by some person legally authorized for that purpose. 7 & 8 W. III. c. 22. *f. 21.* 34 Geo. III. c. 68. *f. 15,* and *hy itat.* 26 Geo. III. c. 60. *f. 16.*

In addition to the above indorsement there shall also be indorsed on the certificate of registry, before two witnesses, the town, place, or parish, where all persons to whom the property in any ship or vessel shall be transferred shall reside; or if such persons usually reside abroad, but in some British factory, then the name of such factory of which such persons are members; or if such persons reside in any foreign town or city, the name of such foreign town or city, and also the names of the house or copartnership in Great Britain or Ireland for or with whom such are agents or partners; and the person to whom the property of such ship or vessel shall be so transferred, or his agent, shall deliver a copy of such indorsement to the person authorized to make the registry, who is to cause an entry to be indorsed on the oath or affidavit upon which the original certificate of registry of such ship or vessel was obtained; and also to make a memorandum in the book of registers, and forthwith give notice to the commissioners of the customs in England or Scotland, under whom they respectively act.

The certificate of registry of such vessel shall be recited in words at length in the bill or instrument of sale thereof, otherwise such bill of sale shall be utterly void. *f. 17.*

As often as the master or commander of any registered vessel shall be changed, the master or owner thereof shall deliver to the person authorized to make such registry at the port where such change shall take place, the certificate of registry belonging to such ship or vessel, who shall indorse and subscribe a memorandum of such change, and shall give notice to the proper officer of the port where such ship or vessel was last registered; who shall likewise make a memorandum of the same in the register book, and give notice to the commissioners of the customs in England and Scotland. *f. 18.*

No owner of any ship or vessel shall be permitted to give any other name thereto than that by which she was first registered. And all owners of registered vessels shall, within one month from the registry, paint in white or yellow letters, of a length not less than four inches, upon a black ground, on some conspicuous part of the stern (provided there shall be sufficient space, but if not, then in letters as large as such space will admit), the name by which such ship or vessel shall have been registered, and the port to

which she belongs, and so keep and preserve the same. And if such owner, or master or commander of such ship or vessel shall wilfully alter, erase, or conceal, or permit the same to be done, unless in the case of square rigged vessels in time of war, or shall in any written or printed paper describe such ship by any other name than that by which she was first registered, or shall verbally describe such ship or vessel by any other name to any officer of the revenue in the due execution of his duty, such owner or commander thereof shall forfeit the sum of 100*l.* s. 19.

By stat. 26 Geo. III. c. 60, all persons who shall apply for a certificate of registry in Great Britain, Guernsey, Jersey, or the Isle of Man, for any ship which shall be built, or whose building shall be completed after the 1st of August 1786, shall produce to the person authorized to grant such certificate a true account under the hand of the builder of the same, of the proper denomination, the time when, and the place where such ship or vessel was built, and an exact account of the tonnage, together with the name of the first purchaser; and also make oath before the person authorized to grant such certificate, that the ship or vessel for which such certificate is required is the same with that so described by the builder. And every person applying for a like certificate in any of his majesty's colonies, plantations, or territories, shall, before such certificate is granted, produce the like account, under the builder's hand, and take the like oath as is required to be produced and taken by persons applying in Great Britain. s. 20, 21.

If any certificate of registry shall have been lost, a register and certificate *de novo*, in the form herein directed, shall be granted for such vessel, according to 15 Geo. II. c. 31; but in all such cases such security shall be given as is directed in this act, and in lieu of the oath prescribed by 15 Geo. II. the like oath shall be taken and subscribed as hereinbefore directed, by the owner or owners of such ships and vessels as are required to be registered by this act. s. 22, 23.

If any ship or vessel shall, after registry, be altered, either in form or burthen, or in any manner whatsoever, such ship or vessel shall be registered *de novo* as soon as she returns to her port, or to any other port in which she may be registered by virtue of this act; on failure whereof such ship or vessel shall be considered as a foreign vessel. s. 24.

The owners of all such ships as shall be condemned as lawful prize, shall, upon registry thereof, before any certificate of registry shall be obtained, produce to the proper officer of the customs a certificate of the condemnation of such vessel, and also a true account in writing of all the particulars contained in the certificate herein-before set forth, to be made and subscribed by one or more skilful persons to be appointed by the court to survey such ship or vessel; and shall also make oath before the said officer, that such ship or vessel is the same ship or vessel mentioned in the certificate. s. 25.

No ship condemned as prize shall be registered in the islands of Guernsey, Jersey, or the Isle of Man, although belonging to his majesty's subjects resident in those islands; but the same shall be registered either at Southampton, Weymouth, Exeter, Plymouth, Falmouth, Liverpool, or Whitehaven, by the collector and comptroller at such port respectively. 26 G. III. c. 60. s. 26.

In all cases where any ship or vessel taken and condemned in any of his majesty's colonies, plantations, or islands aforesaid, shall be registered, and obtain a certificate, an exact account shall be subjoined thereto of the sum for which such ship or vessel shall have been sold, verified upon the

oath of the person applying for such certificate of registry. s. 27.

All certificates, hereafter to be granted in pursuance of this act, shall distinguish whether such ships or vessels be of the built of Great Britain, Guernsey, Jersey, or the Isle of Man, or of the colonies, plantations, islands, or territories aforesaid, or of any foreign country; and shall, if British built, be entitled "Certificate of British plantation registry;" and if foreign built, shall be entitled "Certificate of foreign ship's registry for the European trade, British property;" as the case may be. s. 28.

No ship or vessel, directed by this act to be registered, shall be permitted, after the first arrival at the port to which she belongs, at the expiration of the notice by this act directed, to clear outwards for foreign parts, or coastwise, or to proceed to sea for the purpose of fishing on the coasts, or for any other purpose, as a British ship or vessel, unless the owners thereof shall have obtained a certificate; and in case such ship or vessel depart from such port without being registered, and without having obtained a certificate, every such ship or vessel, with all her guns, furniture, ammunition, tackle, and apparel, shall be subject to forfeiture. s. 32.

If, after the expiration of the before-mentioned notice, any ship or vessel (being square rigged) shall be found in any port within 20 leagues by water from the port to which she belongs, or if any vessel, not square rigged, be found within any port other than that to which she belongs, without having a certificate of registry hereinbefore directed, it shall be lawful for the principal officer of such port, and he is hereby required to detain such until the master or commander shall, if such ship or vessel be under 50 tons, give security by bond in 50*l.* in manner hereinafter directed; and if the same shall exceed 50 and not exceed 100 tons, shall give security by bond in 100*l.*; and if the same shall exceed 100 tons, then until the master or commander shall with one security give bond in 200*l.*, with condition that such master or commander shall forthwith repair with her to the port to which she belongs, and there cause her to be registered, procure a certificate, and deliver to such officer such certificate within the time limited in the condition of such bond; which time is to be fixed according to the distance of the vessel from the port to which she belongs, and the nature of the voyage in which she may be engaged; and on failure of producing such certificate, such bond shall be forfeited; but if the certificate be produced within the time so limited, such bond shall be void. And in case any square rigged vessel shall be found in port, after the expiration of the aforesaid notice, more than 20 leagues distant by water from the port to which she belongs, or that the water at the entrance of the port to which she belongs shall be so shallow as not to admit her entrance, the master or commander shall, within 48 hours after his arrival at such port, make known his arrival to the collector and comptroller of the customs, or other principal officer of such port; and shall require such collector and comptroller to cause his ship or vessel to be surveyed by the proper officer, who shall accordingly make a perfect survey, and certify the several particulars thereof; and such collector and comptroller shall immediately transmit the said certificate of survey to the person authorized to register ships and vessels at the port to which such vessel belongs, who shall register such vessel, and grant certificate of registry; and it shall be lawful for the collector and comptroller, or other principal officer of the customs, in the port where such ship or vessel shall be so found, to detain her until a perfect and accurate survey, in the manner hereinbefore directed, can be made.

The remaining sections of this act relate to penalties upon the

REGISTRY.

the misconduct of officers, forging or altering certificates of registry, mode of recovering penalties, &c.

By 27 G. III. c. 19. s. 4, no oath taken for the sole purpose of acquiring the rights of a citizen or burgher in any foreign city or town in Europe, to be enjoyed during the time that such person taking such oath shall reside in such city or town, and for a limited time after such residence shall have expired, shall be deemed an oath of allegiance to a foreign state, nor inconsistent with the form of the oath upon registry prescribed by 7 & 8 W. III.

Ships belonging to the East India company, or any other body corporate, are to be registered upon the oath subscribed by the secretary of the said company or other body corporate, or by any other officer properly authorized. s. 7.

No vessel whatsoever, not exceeding the burthen of 30 tons, and not having a whole or fixed deck, and being employed solely in the Newfoundland fishery, or on the banks or shores of the provinces of Quebec, Nova Scotia, or New Brunswick, adjacent to the gulf of St. Lawrence, and to the north of cape Canso, or of the islands within the same, or in trading coastwise within the said limits, shall be subject to be registered in pursuance of the said act. s. 8.

Ships built in Newfoundland, and those parts of the provinces of Quebec, Nova Scotia, and New Brunswick, adjacent to the gulf of St. Lawrence, and to the north of cape Canso, or in the islands within the said limits, on account of owners residing in his majesty's European dominions, shall be registered in the above places, upon the husbands or principal agents of the said ships taking the oath required; and such certificates shall be of the same effect as if granted upon the oath of the owners, until such time as they shall arrive in port in any of his majesty's European dominions, where they may be respectively registered upon the oath of the respective owners, but no longer. And whenever such ship shall arrive at any such port in his majesty's European dominions, the certificates of registry, granted in pursuance of this act, shall be null and void, and shall be delivered up to be cancelled; and such ships are hereby required to be respectively registered *de novo* conformably to the requisitions of the preceding act. s. 9.

By 27 G. III. c. 19. s. 13, all ships not registered according to the directions and regulations of the said act, although such ships may be owned by his majesty's subjects, shall be held and deemed as alien ships, and shall in all cases be liable to such and the same penalties and forfeitures as alien ships are by law liable to in similar cases.

By 34 G. III. c. 42, foreign ships and vessels heretofore owned by subjects of the late French king, which in consequence of any capitulation may be put under his majesty's protection at the time of, or in consequence of the surrender of any foreign colony, may be registered as ships condemned as lawful prize, and shall become entitled to the privileges of British ships, under the regulations and restrictions hereafter mentioned. Provided always, that no ship shall be so registered but upon producing a certificate under the hand and seal of the person who commanded in chief, by sea or land, at the time when such foreign colony was surrendered (or in case of the death or departure of any such officer before such certificate shall have been so given, then upon a like certificate under the hand and seal of the person who shall command in chief, by sea or land, at such colony), testifying that such ship or vessel was put under the protection of his majesty at the said time; and upon oath, hereinafter directed, being taken and subscribed before the person authorized to make such registry, by the owner of such ship, if the belong to one person only; or in case there shall be

two joint owners, then by both of such joint owners, if both be resident within 20 miles of the place where such registry is required, or by one of such owners, if one or both of them shall be resident at a greater distance; or if the number of such owners shall exceed two, then by the greater part of them, if the greater number of them shall be resident within 20 miles, not in any case exceeding three of such owners, or by one of such owners, if all shall be resident at a greater distance. Provided that such registry shall, for the island of St. Domingo, be made at the port of Kingston in the island of Jamaica, and for any of the French Leeward islands, in the port of Roseau in the island of Dominica; and the said ports of Kingston and Roseau shall respectively, for the purpose of such registry, be deemed to be the port to which such ship belongs. s. 1.

His majesty, by the advice of his privy council, may at any time, on the arrival of any such ship in Great Britain, upon application made to him, authorize any such ship (without payment of any duty whatever for the said ship, or the sails and other necessary tackle, apparel, and furniture thereof) to be registered, as in the case of a prize-ship, in any port of Great Britain. s. 4.

No person heretofore a subject of the late French king, being a white person, a mulatto, or free negro, shall be employed to navigate any vessel bound from such foreign colony, to any part of his majesty's dominions, or be conveyed as a passenger on board thereof, unless such person shall produce a certificate under the hand and seal of the person who commands in chief in such foreign colony, or at the place therein whence such ship shall sail, testifying that such person has taken the oath of fidelity and allegiance to his majesty; and no negro-slave belonging to any person whatsoever, heretofore a subject of the late French king, shall be so conveyed or employed, but upon a certificate under the hand and seal of his master (which master shall have taken the oath of fidelity and allegiance as aforesaid), certifying the good character of such negro-slave, and testifying that his conduct has been such that he may be safely admitted into the ports of his majesty's dominions; which certificate shall be indorsed by the person who commands in chief his majesty's troops or vessels at the place from whence such ship shall sail, signifying that he has no reason to doubt of the truth thereof; upon pain that the master or commander of such ship shall forfeit 50*l.* for every person respectively employed or conveyed in such ship without having such certificate. s. 5.

By 34 G. III. c. 68, no goods, wares, or merchandizes whatever shall, from the expiration of six months after the conclusion of the present war, be imported into, or exported from, any port or place in Great Britain, or Guernsey, Jersey, Alderney, Sark, or Man, to any other port or place of the same, on board any ship or vessel which, by law, is or shall be required to be registered as a British ship or vessel, unless such ship or vessel shall be navigated by a master and three-fourths at least of the mariners British subjects. Nor, from the expiration of six months from the conclusion of the present war, shall any ship or vessel, which by law is or shall be required to be registered as a British ship or vessel, be navigated but by a master and three-fourths of the mariners at least British subjects, except as hereinafter provided. s. 1, 2, 3.

No goods, wares, or merchandizes whatever shall be carried from any port in Great Britain, or Guernsey, Jersey, Alderney, Sark, or Man, to any other port or place of the same, nor shall any ship be permitted to sail in ballast from or to any of the aforesaid ports, nor be employed in fishing on the said coasts, unless such ship shall be wholly and solely

REGISTRY.

manned with and navigated by a master and mariners all British subjects. The commissioners of the customs may, however, by licence under their hands, authorise any such ship or vessel employed in fishing on the coast of Great Britain, or of the islands of Guernsey, Jersey, Alderney, Sark, or Man, to have on board any foreign mariners for the purpose of instructing the British mariners thereof in the art of fishing; such foreign mariners not exceeding one-fourth of the number of mariners on board such vessel, except in cases of sickness, death, desertion, or capture. f. 5.

By stat. 34 G. III. c. 68, no person shall hereafter be deemed to be qualified to be the master of a British ship, or to be a British sailor, seaman, or mariner, except the natural-born subjects of his majesty, or persons naturalized by any act of parliament, or made denizens by letters of denization; or except persons who have become his majesty's subjects by virtue of conquest or cession of some newly acquired country, and who shall have taken the oath of allegiance to his majesty, or the oath of fidelity required by the treaty of capitulation, by which such newly acquired country came into his majesty's possession, except as is hereinafter provided. f. 6.

But every foreign seaman serving on board any of his majesty's ships in time of war, for the space of three years, who shall also take the oath of allegiance, shall be entitled to be employed as a master of a British ship or vessel, or as a British mariner on board any British ship, upon delivering certificates from the captains under whom he served, of the time he shall have served, and of his faithful service and good behaviour, and a certificate of his having taken the oath of allegiance. f. 7.

No person who has taken an oath of allegiance to any foreign state shall be deemed qualified to be the master of a British ship or vessel, or a British sailor, unless such person shall have taken such oath of allegiance before he became so qualified; and any person who shall, after having become disqualified by taking such oath of allegiance, take the charge or command of any British ship or vessel, shall for every such offence forfeit one hundred pounds; and if such person shall engage to serve as a British seaman or mariner on board any such ship, he shall forfeit ten pounds, unless the owners shall shew that such disqualifications were unknown to them or their agents at the time of engaging such master or sailor to serve on board such ship or vessel. Except in the navigation on the seas of America and the West Indies, any negroes belonging to his majesty's subjects, and in the seas to the eastward of the Cape of Good Hope, Lascars and other natives of any of the countries to the eastward of the Cape of Good Hope, may be employed as British sailors, seamen, or mariners, in manner heretofore practised. Provided nevertheless, that no negro belonging to any person who has become a subject of his majesty, in manner before described, in any of the islands or colonies late under the dominion of the French, shall be entitled to be employed in manner before mentioned as a British sailor, seaman, or mariner, unless all the conditions required by the 34th G. III. c. 42, shall have been complied with during the continuance of the said act.

By the 13th G. II. c. 3, his majesty in time of war may permit merchant ships to be navigated by foreigners, provided one-fourth of the crew be British subjects.

If any goods, wares, or merchandize whatever shall be imported or exported, or carried coastwise, contrary to the provisions of this act, or any of them, all such goods, wares, and merchandize, and also the ship or vessel, with all her guns, furniture, ammunition, tackle, and apparel, shall be forfeited; and if any ship shall sail in ballast, or shall sail

to be employed in fishing along the coast in manner herein before mentioned, or, being required to be manned and navigated with a master and a certain proportion of British mariners, in manner herein before directed, shall not be manned and navigated accordingly, such ship or vessel, with all her guns, furniture, ammunition, tackle, and apparel, and all the goods, wares, and merchandize on board, shall be forfeited. f. 10.

All goods, wares, and merchandize, and all vessels, forfeited by this act, may be seized by the commander of any of his majesty's ships of war, or any commissioned, warrant, or petty officer specially appointed, or by any officer or officers of his majesty's customs or excise.

If any British ship shall be found at sea, having on board a greater number of foreign mariners than is allowed by this act, or any law in force or hereafter to be made, and the master of such vessel shall produce a certificate of the actual necessity of engaging such foreign mariners in some foreign port, by occasion of the sickness, death, or desertion of the like number of British mariners, or of the same having been taken prisoners during his voyage, and that British mariners could not be engaged at such foreign port to supply their place, and that for the safe navigation of such ship or vessel, it became necessary to engage and employ such foreign mariners, under the hand of his majesty's consul at the foreign port where the mariners are so engaged, or, if there be no such consul there, under the hands of two known British merchants at such foreign port, no seizures shall be made by the persons authorized under this act, nor shall such ships be molested or detained at sea; but such persons shall indorse the certificate so produced, testifying the production thereof, and when and where met with at sea, and that the number of foreign mariners correspond with the certificate of such British consul, or such known British merchants, for the consideration and investigation of the commissioners of his majesty's customs in England and Scotland respectively.

By 34 G. III. c. 68. f. 14, no transfer, nor agreement for transfer, of the property in any ship or vessel, either in whole or in part, shall be made but by a bill of sale or instrument in writing, which shall contain a recital in words at length of the certificate of registry.

If a ship be at sea at the time when the transfer is made, so that an indorsement and certificate cannot be immediately made, the sale, or contract for sale, shall, notwithstanding, be made by some instrument in writing, and a copy thereof shall be delivered to the person authorized to make registry, who is to indorse an entry thereof on the oath or affidavit, make a memorandum in the book of registers, and give notice to the commissioners of the customs as before directed: and within ten days after the ship returns to port, an indorsement shall be made on the certificate of registry, and a copy thereof delivered as before-mentioned; otherwise such sale shall, to all intents and purposes, be void. f. 16.

Where the owner of any ship shall, at the time of transferring the property in any ships, be abroad, so that an indorsement, &c. or such bill of sale, cannot be immediately made, the same may be done at any time within six months after such transfer, in which case, within ten days after the arrival of the owner or his agent in this kingdom, (if the ship be in any port thereof, and if not, within ten days after such ship's arrival) an indorsement on the certificate of registry shall be made, &c. as before directed. f. 17.

Masters of ships refusing to deliver up the certificate of registry to the proper person empowered to make registry, upon being required so to do by the owner or owners, or the major part of the owners, (if such master have not any property

perty therein,) or by the other owner or owners, or major part thereof, (if such master have any share therein,) and upon oath being made by such owner, owners, or major part thereof, before any justice of the peace near where such refusal shall be, such justice may grant his warrant to bring the master before him; and if it shall appear that the said certificate is *wilfully* detained, such master shall pay one hundred pounds, and on failure of payment shall be committed to the common gaol, for not less than six months, nor more than twelve. § 18.

Upon the justice's certifying the above *wilful* refusal of the master of any vessel to deliver up the certificate to the person authorized to make registry, he shall register the said ship *de novo*, the terms and conditions of the law being complied with. § 19.

When property in any ship or vessel belonging to any of his majesty's subjects shall be transferred by sale, and such vessel shall be required to be registered *de novo*, it shall not be done unless there be produced to the register, the bill or other instrument of sale. Provided always, that the commissioners of customs, and the governor, lieutenant-governor, or commander-in-chief for the time being of the islands of Guernsey or Jersey, or of any colony, plantation, island, or territory belonging to his majesty, may, upon due consideration of the particular circumstances of the case, give directions for the registering such vessel *de novo*, and granting a certificate of such registry, notwithstanding such bill or other instrument of sale shall not have been produced as aforesaid; and such registry shall be made, and such certificate thereof shall be accordingly granted, if all the other regulations required by the laws in force concerning the registry of ships *de novo* be complied with. § 20.

If there shall be any alteration of property at the same port, and the owner shall be desirous of having the ship registered *de novo*, such ship may be so registered, provided all the rules, regulations, and conditions are complied with relative to vessels registered *de novo*. § 21.

In case of any transfer of property in any ship whilst at sea, such ship shall proceed directly to the port for which the cargo then on board is destined, and shall sail from thence to the port of his majesty's dominions to which she belongs, or to any other such port in which she may be legally registered; and such ship may take on board in the port for which her original cargo was destined, or in any other port in the course of her voyage home, such cargo as may be legally carried to such port of his majesty's dominions where she may be so registered *de novo*. And if such transfer of property shall be made while such ship is in any foreign port, as soon as the master of such ship shall become acquainted therewith, such ship, after having delivered the cargo then on board at the port for which she is destined, shall sail thencefrom to the port to which she belongs, or to any other such port in which she may be legally registered; and may take on board at the port for which her original cargo was so destined, or at any other port in the course of her voyage home, such cargo as may be legally carried to such port of his majesty's dominions where she may be so registered *de novo*. And if such transfer of property shall be made while such ship is on a fishing voyage, as soon as the master of such ship shall become acquainted therewith, such ship, after having finished such fishing voyage, without touching at any foreign port, except for the purpose of repairs or refreshments, or for delivering any part of her cargo, shall sail to the port of his majesty's dominions to which she belongs, or to any other such port where she may be legally registered, and may take on board at the foreign port or ports last described, or at any other ports in the course of

her voyage home, such cargo as may be legally carried to such port of his majesty's dominions; and every such ship as aforesaid shall be registered *de novo*, as soon as she returns to the port of his majesty's dominions to which she belongs, or to any such port in which she may be legally registered by virtue of the said act; on failure whereof such ship shall be deemed from thenceforth to be a foreign ship or vessel, and shall not again be registered, or be entitled to the privilege of a British ship or vessel, unless upon special representation of the circumstances of the case to the commissioners of customs, or to the governor, lieutenant-governor, or commander-in-chief for the time being of the islands of Guernsey or Jersey, or of any colony, plantation, island, or territory to his majesty belonging, as the case may be: provided nevertheless, that in no case the ship or vessel of which the property is so transferred, shall be entitled to the privileges of a British ship or vessel, unless she shall return to the port to which she belongs, or to such other port in which she may be registered *de novo*, within the period of twelve months after the date of such transfer of property, if such ship shall not be on a voyage to the east of the Cape of Good Hope, or to the west of cape Horn; or within two years, if the ship is on the above voyages at the time such transfer of property shall take place, except by the order of the said commissioners, governor, lieutenant-governor, or commander-in-chief respectively. § 22. See *Marine INSURANCES*, and *POLICY*.

REGIUS PROFESSORS. King Henry VIII. founded five lectures in each of our universities: *viz.* of Divinity, Hebrew, Greek, Law, and Physic; the readers of which lectures are in the university statutes called *regii professores*.

REGIUS, in *Medicine*. See **JAUNDICE**.

REGLE de l'Orgave, Fr., a rule for accompanying the octave ascending and descending in the base; giving to each note of the scale its appropriate harmony in every key. This rule, well known and practised in the 24 keys, major and minor, will enable students in thorough-base to figure a base themselves, and to accompany modern music without figures.

It is disputed in France who was the inventor of this rule: Rameau and Rousseau assign it to De Laire, M. Laborde to Campion. "This formula," says Rousseau, "was first published by De Laire in 1700." If this date could be ascertained, it would remove all doubts concerning the author of the rule; as Campion's "Treatise of Accompaniment" is not pretended to have appeared till after 1705.

This rule ascertains what chords or harmony belong to every diatonic movement of the base, ascending and descending. See **ACCOMPANIMENT**, or **THOROUGH-BASE**; where the base will be figured, and the chords written over it. We confine the infallibility of this rule to modern music, as no provision is made for 4ths and 9ths, which so frequently occur in Corelli, Geminiani, and Handel. But these discords, and several other combinations, are considered in the articles **COUNTERPOINT** and **ACCOMPANIMENT**, or *Thorough-base*; which see.

By this formula it will appear, that to the key-note there is always a common chord; to the 2d of the key, a $\frac{6}{3}$; to the 3d of the key, a 6th; to the 4th of the key, a $\frac{6}{4}$; to the 5th of the key, a common chord. Thus far the chords are rigorously in one key; but in order to connect the 6th to the 5th, Rameau gives the chord of the $\frac{6}{3}$ to the 6th, as in descending, which makes it the 2d of a new key; but then to recover the modulation into the original key, he gives $\frac{6}{4}$ to the 7th or *note sensible* of the key, and then terminates

minates the scale by a common chord to the octave of the key-note.

In descending, it is necessary to imagine the harmony in the 5th of the key for the four first notes: as, supposing the scale to be in C major, after repeating the common chord to the octave, the 7th of C must be regarded as 3d of the key of G, and be only accompanied by the 6th. A, as 2d of G, by a $\frac{6}{3}$, as in ascending; and the 5th of the key by a common chord, or close in G. The 4th of the key in descending has a $\frac{6}{2}$ or chord of the 5th of the key repeated; the next three chords are the same as in ascending.

In minor keys, in all which supposing A natural to be the archetype, the chords are much the same; only whenever the 7th of the key is wanting in the ascending scale, it must be accidentally sharp: as to A, a common chord minor; to B, the 2d of the key, a $\frac{6}{3}$; to the 3d of the key, a 6th; to the 4th, a $\frac{6}{2}$; to the 5th, a common chord, with a sharp 3d; to the 6th, if natural, a 6th; if sharp, a $\frac{6}{3}$; to the 7th sharp, $\frac{6}{2}$, and a common chord to the octave.

In descending, to the 7th natural, a 6th; to the minor 6th, a $\frac{7}{3}$, or 6 doubling the 3d; to the 5th of the key, a sharp 3d; to the 4th of the key, the same chord, or $\frac{6}{2}+$; and to the three last, the same as in ascending.

These chords will be more clearly comprehended in notation on the thorough-bass plates, to which we refer.

Though the *regle de l'octave* only provides for the regular ascent and descent of the bass in plain counterpoint, we know, by long experience, that it teaches more thorough-bass and counterpoint in a short time, than any other rule that has been proposed since the laws of harmony were settled. See THOROUGH-BASS, ACCOMPANIMENT, and COMPOSITION.

REGLET, or RIGLET, in *Architecture*, a little flat narrow moulding, used chiefly in compartments, and pannels, to separate the parts or members from one another, and to form knots, frets, and other ornaments.

The word is a diminutive of the French, *regle*, rule.

The reglet, according to Daviler, differs from the *fillet* and *listel*, in that it projects equally, like a ruler.

REGLETS, or *Riglets*, in *Printing*, are thin rulers, or slips of wood, of different dimensions, placed in the chase, between the pages, and at the extremes of them, to keep them asunder, and to hold them tight.

The reglets make the chief part of what they call the *furniture of the chase*. See CHASE.

They are particularly denominated from the place they hold in respect of the pages, *head-sticks*, *gutter-sticks*, &c.

The term reglets is also used abroad for a ruler of metal, three quarters of an inch long, but which may be lengthened out by joining several together; used to separate the columns, in books that have several in the same page; as also for lines to place the notes on, in printing of music. See PRINTING.

Reglet is also used for a little thin slip of wood, occasionally, though seldom, used by compositors for the press to take off the lines from the composing-stick, and place them on the galley, where the lines are of an extraordinary length: and where the lines are at great distances, those distances are made by leaving a reglet between each line, when printed.

REGMALARD, in *Geography*, a town of France, in the department of the Orne; 9 miles E.N.E. of Bellesme.

REGNANO, a town of Naples, in Capitanata; 16 miles from Manfredonia.

REGNANT QUEEN. See QUEEN.

REGNARD, JOHN-FRANCIS, in *Biography*, a French poet and writer of comedy, was born of a good family, at Paris, in 1647. His earliest passion was that for travelling, and he first made the tour of Italy. On his return, in an English ship, the vessel was taken by the Algerines, and the crew made slaves at Algiers. Regnard, by his skill in cookery, ingratiated himself with his master: he possessed another art, which had nearly proved fatal to him. His person and manners recommended him to the attention of the ladies, whose advances he encouraged, and being discovered, the alternative was given him of being burnt to death or becoming a disciple of the Koran. He was, however, released from this difficulty by the interposition of the French consul, and the proper application of a considerable bribe. He gained his liberty, and returned to France, and in 1681 departed upon a new tour to the northern countries of Europe. After an absence of three years he came back to Paris, and settled quietly, with the view of cultivating his taste for literary pursuits. He composed a number of comedies for the French theatre, which were acted with success, and which, in the general opinion, placed him next to Moliere in true comic humour. Gaiety is the predominant character of Regnard's comedies, which is sometimes maintained at the expence of morality. He excelled not less in the elevated or genteel comedy, than in the low, or familiar. His two best pieces are said to be "Le Joueur," and "Le Legataire;" for describing, to the life, the scenes of the first, he was extremely qualified, being himself a lucky gambler. He wrote eight comedies, some pieces for the Italian theatre, and an opera. He also published miscellaneous poems, consisting of satires, epistles, &c. In prose he gave a relation of his travels, of which the only part that excited much interest was his account of Lapland. Regnard died at the age of 62. His works have been printed collectively, of which the best edition is that of Paris, in 1790, in 4 vols. 8vo.

REGNAVADSOE, in *Geography*, a small island in the North sea, near the coast of Norway. N. lat. 69° 50'.

REGNI, in *Ancient Geography*, a name given to the ancient inhabitants of Surrey and Suffex, and perhaps of part of Hampshire. They were seated E. of the Belgæ, and S. of the Atrabatii. As these people possessed so large a tract of the sea-coast in the south part of this island, it is very probable that they had come from the continent, and settled here not very long before the Roman invasion, perhaps at the same time with their neighbours the Belgæ. The Belgæ and the Regni had been near neighbours on the continent; the one having migrated from the country of the Sueffiones, now Soissons, and the other from the country of the Rhemi, now Reims. The Regni, like all the other Belgic Britons, early submitted to the Roman power, and continued steady in their obedience, without engaging in any revolt. It is not known who was sovereign of the Regni when they submitted to the Romans, but soon after their submission, they were put under the government of Cogidunus, king of the Dobuni. For this prince, who was then very young, had got so much into favour with the emperor Claudius, and his ministers, that he was not only allowed to keep his own dominions, but he had several other neighbouring states put under his authority. It seems probable, from a famous inscription discovered at Chichester, that Cogidunus governed the Regni in quality of the emperor's lieutenant, or legatus Augusti; for in that inscription he is so styled. He continued a faithful and useful friend and ally to the Romans above 60 years, and thus he was so much endeared to them,

that,

that, according to their custom in other countries, they permitted his posterity to succeed him, perhaps for several generations. Although the Regni were very early and very obedient subjects of the Roman empire, yet as they were long after under the immediate government of British princes, few of the Romans seem to have settled among them. This is, without doubt, the reason that we meet with so few vestiges of those great and active people in those countries which were anciently inhabited by the Regni. Chichester was certainly a considerable place in the time of the Romans, and probably the capital of the Regni, which led the Romans to call it Regnum. However, Camden, Gale, Baxter, and others, are unanimous in fixing Regnum, the capital of the Regni, at Ringwood; but Mr. Horsley has produced several reasons for supposing it to have been situated where Chichester now stands. The Neomagus of Ptolemy, and the Noviomagus of the Itinerary, was a city of the Regni, and it is generally placed at Woodcote, near Croydon, in Surrey; though Mr. Baxter and some other antiquaries contend for Ravenham, in Kent. In the most perfect state of the Roman government in Britain, the country of the Regni made a part of the province called Flavia Cæsariensis, and was governed by the president of that province.

REGNIER, MATHURIN, in *Biography*, a French poet, was born at Chartres in 1573. He is said to have displayed, at a very early period, a great propensity to satire, which his father in vain attempted to repress by chastisement. The exercise of his satirical talents procured him patrons, among whom were the cardinal Francis de Joyeuse, and Philip de Bethune, both of whom he accompanied to Rome. By the interest of these great men he received considerable preferment in the church, but the dignity and gravity of the clerical character was no restraint upon his pleasures, and he died at the age of forty, worn out with licentious practices. The works of Regnier consist of satires, epistles, elegies, stanzas, odes, &c.: of these his satires are most esteemed, and they were thought to make a kind of epoch in French poetry. The poems of Regnier have been frequently printed; the best editions are those of Rouen, 1729, and of London, 1734, with remarks.

REGNIER-DESMARAIS, FRANCIS-SERAPHIN, a French author of considerable reputation, was born at Paris in 1632, of a family originally from Saintonge. Being the younger son of a numerous family, he had to depend solely upon his own exertions for making his way in the world, and he successively attached himself to several persons of rank, whom he accompanied in their travels. Making a proper use of his opportunities, he acquired a knowledge of the Italian and Spanish languages, and he became so much a master of the former, that when he attended the duke of Crequi on his embassy to Rome, in 1662, he wrote the official letters in Italian with so much purity, that they were not known to be the compositions of a foreigner. But he obtained a still greater triumph, by passing upon the academicians of Della Crusca one of his own odes for a newly discovered piece of Petrarch. In consequence of this he was elected, in 1667, a member of that celebrated academy. At the age of thirty-six he took ecclesiastical orders, for the purpose of enjoying a priory given him by Lewis XIV., as a recompense for his public services, and in 1670 he was admitted a member of the French Academy, in the hope that he might become a contributor in the compilation of their dictionary. Soon after this, at the request of the Jesuits, he translated from the Spanish language a treatise "On Christian Perfection." In his capacity of academician, Regnier displayed so much activity and zeal, that on the death of Mezerai, in 1684, he was appointed to succeed him as se-

cretary. When the dictionary was completed, the secretary by order of the Academy, drew up a preface, and an epistle dedicatory to the king; but, during his absence, other members, who were inspired with the desire of emulating him in this honour, procured a preference for their own productions. This disappointment drew from Regnier some critical remarks upon the rival performances, tinged with that cavilling and disputatious spirit, to which it appears he so often gave way, that he obtained the title of the abbé Pertinax. He was so attached to his own opinion, that he could seldom be prevailed upon to give up his point, or to drop a dispute. Fontenelle, being once present at an academical discussion, in which Regnier was warmly engaged, exclaimed, "this is a dispute that might be prevented from ever ending, and therefore it ought to be ended immediately." Regnier obtained several benefices, and would probably have been promoted to the very highest dignity in the church, had he not been suspected of translating a scene in the "Pastor Fido," which seems to inculcate a licentious morality, and likewise suspected of writing a still more objectionable copy of verses. He was occasionally employed in public business. He died at Paris in 1713, at the age of 81. He had drawn up a great many of the most important articles in the dictionary of the French academy, and he published, as the result of his long study of the principles of the French language, his "Grammaire Française," in 2 vols. 12mo., which is considered as a very valuable performance. His other works in prose were "L'Histoire des Dèmeles de la France, avec la Cour de Rome, au Sujet de l'Affaire des Corfes." Translations of several of Cicero's pieces. In verse he gave an Italian version of the Odes of Anacreon, and miscellaneous poems in Latin, French, Italian, and Spanish. His French poems are varied, ingenious, and well turned, but they are allowed not to possess much fire or force. We have alluded to the abbe's unyielding disposition: but it must be added, that he was steadfast in his friendships, inflexibly upright, and scrupulously veracious. The last quality, says his biographer, he nobly expressed, when, on being urged to violate the truth in favour of a man in power, and under the penalty of losing his friendship, he said, "I had rather quarrel with him than myself."

REGNO, in *Geography*, a town of Sweden, in East Gothland; 28 miles N. of Nordkiöping.

REGNO, *Ne exeat*, in *Law*. See *NE exeat*, &c.

REGNUM. See REGNI.

REGNUM *Ecclesiasticum*, a denomination given to one of the two kingdoms, which the clergy supposed to have existed in some countries: this, they pretended, was absolute and independent of any but the pope, comprehending ecclesiastical men and causes, and exempt from the secular magistrature: the other was a *regnum seculare* of the king or civil magistrate, which was subordinate and subject to the ecclesiastical kingdom: but these usurpations were exterminated here by Henry VIII. 2 Hale's Hist. P. C. 324.

REGNY, in *Geography*, a town of France, in the department of the Rhône and Loire; seven miles E. of Roanne.

REGOLA, Ital., a rule in music, a canon.

REGOLA *Armonica*, a monochord.

REGOLETS, in *Geography*, a passage from the gulf of Mexico into lake Pontchartrain, about ten miles long, and three or four hundred yards wide.

REGRADATION, REGRADATIO. See DEGRADATION.

REGRATOR, REGRATARIUS, a law-word, formerly used for one that bought wholesale, or by the great, and sold again by retail.

The term is now chiefly used, as it is described by stat. 5 & 6 Edw. VI. cap. 14. to denote one that buys corn, or other dead victuals, in any market, and sells them again, in the same market, or within four miles of the place.

Regrating is an offence against the public, and is liable, by the statute just cited, to the same penalty with engrossing and forestalling.

REGRATOR is also used for a person who refurbishes up old moveables, to make them pass for new. See FRIPPERY.

Among masons, &c. to regrate is to take off the outer surface of an old hewn stone, with the hammer and ripe, in order to whiten and make it look fresh again.

REGRESSION, or RETROGRADATION of curves, &c. See RETROGRADATION.

REGUINY, in *Geography*, a town of France, in the department of the Morbihan; five miles N.W. of Josselin.

REGULA. See RULE.

REGULA, in *Architecture*. See REGLET.

REGULAR, REGULARIS, denotes the relation of any thing that is agreeable or conformable to the rules of art.

In this sense, the word stands opposed to *irregular*, or anomalous.

Thus we say, a regular proceeding, a regular building, regular poem, regular verb, &c.

REGULAR *Figure*, in *Geometry*, is a figure which is both equilateral and equiangular; *i. e.* whose sides, and consequently its angles, are all equal.

The equilateral triangle and square are regular figures. All other regular figures, consisting of more than four sides, are called regular polygons.

Every regular figure may be inscribed in a *circle*; which see.

For the dimensions, properties, &c. of regular figures, see POLYGON.

REGULAR *Body*, called also *Platonic body*, is a solid terminated on all sides by regular and equal planes, and whose solid angles are all equal.

The regular bodies are five in number; *viz.* the *cube*, which consists of six equal squares; the *tetrahedron*, or regular triangular pyramid, having four equal triangular faces; the *octahedron*, having eight; the *dodecahedron*, having twelve pentagonal faces; and the *icohedron*, having twenty triangular faces. See each under its proper article. Besides these five, there can be no other regular bodies in nature.

To measure the surface and solidity, &c. of the five regular bodies.—The solidity, &c. of the cube is shewn under the article CUBE. The tetrahedron being a pyramid, and the octahedron a double pyramid; and the icohedron consisting of twenty triangular pyramids; and the dodecahedron of twelve quinquangular ones, whose bases are in the surface of the icohedron and dodecahedron, and their vertices meeting in a centre; the solidities of these bodies are all found from what we have shewn under PYRAMID.

1. Their surface is had by finding the area of one of the planes, from the lines that bound it; and multiplying the area thus found by the number from which the body is denominated: *e. gr.* for the tetrahedron, by 4; for the hexahedron, or cube, by 6; for the octahedron, by 8; for the dodecahedron, by 12; and for the icohedron, by 20. The product is the superficial area.

Or, the superficial contents of any of the five Platonic bodies may be had by the following proportion; as 1 is to the square of the side of the given Platonic body,

so is $\left\{ \begin{array}{l} 1.7320508 \\ 3.4641016 \\ 6.0000000 \\ 8.6602540 \\ 20.6457788 \end{array} \right\}$ to the superficial content of the $\left\{ \begin{array}{l} \text{tetrahedron.} \\ \text{octahedron.} \\ \text{hexahedron.} \\ \text{icohedron.} \\ \text{dodecahedron.} \end{array} \right\}$

Hence we have the following rule: multiply the proper tabular area, taken from the preceding table, by the square of the side of the given solid, for the superficies.

2. The diameter of a sphere being given, to find the side of any of the Platonic bodies, that may be either inscribed in the sphere, or circumscribed about the sphere, or that is equal to the sphere.

As 1 is to the number in the following table, respecting the thing sought, so is the diameter of the given sphere to the side of the Platonic body sought.

The diameter of a sphere being unity, the side of a	That may be inscribed in the sphere, is	That may be circumscribed about the sphere, is	That is equal to the sphere, is
Tetrahedron	0.816497	2.44948	1.64417
Octahedron	0.707107	1.22474	1.03576
Hexahedron	0.577350	1.00000	0.88610
Icophedron	0.525731	0.66158	0.62153
Dodecahedron	0.356822	0.44903	0.40883

3. The side of any of the five Platonic bodies being given, to find the diameter of the sphere, that may be inscribed in that body, or circumscribed about it, or that is equal to it. As the respective number, in the above table, under the title, *inscribed, circumscribed, or equal*, is to 1, so is the side of the given Platonic body to the diameter of its inscribed, circumscribed, or equal sphere, in solidity.

4. The side of any of the five Platonic bodies being given, to find the side of either of the Platonic bodies, which are equal in solidity to that of the given body. As the number under the title *equal*, against the given Platonic body, is to the number under the same title, against the body whose side is sought, so is the side of the given Platonic body to the side of the Platonic body sought.

5. To find the solid contents of any of the five Platonic bodies. As 1 is to the cube of the side of any of these bodies, so is 0.1178513 to the solid content of a tetrahedron, 0.4174045 to that of the octahedron, 1.0000000 to that of the hexahedron, 2.1816950 to that of the icohedron, and 7.6631189 to the solid content of the dodecahedron.

Hence we have the following rule: multiply the tabular solidity by the cube of the side or linear edge, for the solid content. The demonstration of this rule, and that for the superficies above given, is as follows:

The tabular numbers denote the surface and solidity of each body, when its side or edge is one; and, because, in similar bodies, the surfaces are as the squares of the linear edges, and the solidities as the cubes of the same, the truth of the rules is manifest.

If one of these bodies be required to be cut out of the sphere of any diameter, let *dr* (*Plate XII. Geometry, fig. 9.*) be the diameter of any sphere, and *da* one-third of it, = *ab = br*. Erect the perpendiculars *ae, cf*, and *bg*; and draw *de, df, er, fr*, and *gr*; then will (1) *re* be the side of the tetrahedron; (2) *df*, the side of the hexahedron; (3) *de*, the side of the octahedron; (4) and cutting *de* in extreme and mean proportion in *b, db* will be the side of the dodecahedron; (5) setting the diameter *dr* up perpendicular at *r*, from the centre *c*, to its top, draw the line *cg*, cutting

cutting the circle in g , let fall the perpendicular $g b$; fo is $b r$ the fide of the icofahedron.

REGULAR *Curve*. See CURVE.

REGULAR *Architecture, Fortification, &c.* See ARCHITECTURE, and FORTIFICATION.

REGULAR *Attacks*, in a fiede, are thofe that are made in form, or by regular approaches. See PARALLELS.

REGULAR *Baftion*. See BASTION.

REGULAR *Place*. See PLACE.

REGULAR, in the *Monaftic Senfe*, denotes a perfon who has made the vows in fome religious houfe. See RELIGIOUS and VOW.

Under regulars are comprehended the whole body of monks, friars, and mendicants, &c.

The denunciation of regulars, in this cafe, arifes hence, that they are bound to obferve the regula or rule of the order they are entered into. Hence,

REGULAR *Prieft* is ufed for a prieft who is in fome religious order, in oppofition to a *fecular* prieft, who lives in the world, or at large.

A cardinal is reputed both regular and fecular, and is intitled to the privileges of both ftates.

Regulars may be promoted to biftropries and archbiftropries, as well as feculars; but their promotion fecularizes them; the epifcopal dignity difpenfing them from the obfervation of the rule of which they had before made profeflion.

REGULAR *Abbots*. See ABBOT.

REGULAR *Benefices*, are fuch as can only be held by monks or religious; or at leaft, *per cupientem profiteri*, by a perfon defirous to embrace the monaftic life. See BENEFICE.

It is a maxim in the Romifh canon law, *regularia regularibus, i. e.* regular benefices are to be conferred on regular priefts. The abbeyes that are chiefs of their refpective orders are all regular, and can only be ferved by monks and cardinals. All benefices are prefumed to be fecular, unlefs they be proved regular.

Anciently the regular benefices were almoft all conferred by way of adminiftration or curacy; the religious incumbents being always *ad manum* to their fuperiors, who difplac'd them at pleafure. Hence the common maxim among the canonifts, *omne beneficium regulare manuale*.

The benefices appropriated to regulars are abbeyes, conventual priories, fimple priories, and clauftal offices. They may be conferred on feculars *in commendam*.

REGULAR *Canons*. See CANON.

REGULAR *Places*, are thofe within the boundary or inclofure of the convent; as the cloifter, dormitory, chapter, and refectory. In oppofition to thofe deftined for guefts, and for the neceffaries of the houfe, which are reputed without the inclofure.

REGULAR *Corporation*. See CORPORATION.

REGULATION, a rule or order prefcribed by a fuperior, for the uniform and orderly management of fome branch of policy, juftice, or the like.

REGULATOR of a *Watch*, is a fmall fpring belonging to the balance, ferving to adjust the going, and to make it go either falter or flower.

REGULATOR of *Velocity*, in *Mechanics*, is a contrivance for regulating or governing the motion of a mill, or other large machine, by means of which it will always be caufed to preferve an equable and regular velocity in the motion of its parts, notwithstanding any accidental increafe of the moving force, or decreafe of the refiftance that may occafionally arife. A regulator muft be connected with fome lever, or other parts of the machine, which commands the

supply of whatever conftitutes its moving force, as the fhuttle of a water-wheel, the fail-cloth of a wind-mill, or valve of a fteam-engine; and it fhould have the property of acting fuddenly upon this lever, or other part, the inflant any increafe or decreafe of velocity in the motion takes place, either to elevate or depreff it, and thus regulate the fupply in a degree proportioned to the quantity of alteration in the velocity; and it is by the fenfibility and accuracy of the regulator in this refpect that its perfection is eftimated.

The regulator moft commonly ufed is called a *governor*. This confifts of two or more pendulums fufpended from joints, which are fupported upon a vertical axis: this being caufed to revolve by the machine, and the pendulums accompanying it, the balls will, by the centrifugal force, recede from the axis or centre a quantity proportioned to the velocity of the motion and length of the pendulum: then, on any acceffion of the motion, they recede ftill further from the axis, or *vice verfa*, if the velocity diminifhes. This motion is contrived to actuate the lever which regulates the velocity of the machine in a fteam-engine: it is connected with the valve which admits the fteam from the boiler to the cylinder, in a water-wheel with the fhuttle, through which the water flows, or in a wind-mill with the mill-ftones, or fail-cloths. See a farther defcription under MILL-WORK, STEAM-Engine, and WINDMILL.

The principle of the governor is the fame with the circular or conical pendulum, of which Huygens has laid claim to the invention, as well as of the long pendulum for regulating clocks, who fays he difcovered it nearly at the fame time as the other. The conical pendulum circulates feconds when of the fame length with the common pendulum, which will vibrate only half feconds. To explain it, we muft fuppoze a ball or weight to be fufpended by a ftring or rod, fo that the ball can defcribe in a horizontal circle by a motion of the rod round a vertical axis, with which the centre of fufpenfion coincides. In this motion the rod of the pendulum will defcribe the furface of a cone, of which the point of fufpenfion is the vertex, and the horizontal circle which the ball defcribes is the bafe: it is hence called the circular or conical pendulum. The ball has liberty to recede from, or approach to, the axis, by moving upon its centre of fufpenfion, and thus the circle the ball defcribes will be enlarged or diminifhed; and it is this circumftance which gives it the property of circulating or performing a revolution always in the fame fpace of time which a fimple pendulum of four times the length would vibrate; for this takes place equally whether the ball is extended to defcribe a large circle, or retracted to revolve in a fmall one; though, it fhould be obferved, that this is only true in the fuppoftion that the pendulum-ball, in moving from the vertical axis upon its centre, will defcribe a parabola inftead of a circle, in the fame manner as the ball of a common pendulum is required to move in the arc of a cycloid inftead of a circle, to caufe all the vibrations, both long and fhort, to be performed in equal fpaces of time. Mr. Martin has, in his *Inftitutions*, given a very complete explanation of the principle of this pendulum, by fuppofting an inverted parabola, with its axis placed in a vertical pofition; then fuppofting a bowl or vefel excavated by the revolution of this figure upon its axis a paraboloid will be formed. A heavy globe or ball being put in this bowl, may, by agitating the vefel, be caufed to perform a revolution in a horizontal circle within the vefel, and it will be found to circulate in the fame period of time, whether it defcribes a fmall circle near the bottom of the vefel, or a large circle in its upper part, where the diameter is larger.

REGULATOR.

The governor or flying-ball is the regulator most generally used in machinery, although there are other means which, in particular instances, are preferable, from the circumstance of their possessing a greater power to operate upon the regulating part of the machine. One of these, called the water-regulator, consists of a pump, which, being worked by the machine, will raise water into a cistern, from which a constant stream flows off by a pipe and cock; a float is placed upon the surface of the water in the cistern, and this communicates with the steam-valve of the engine, or shuttle of the water-wheel. The operation of this regulator is easily explained, for the pump will raise a quantity of water exactly proportioned to the velocity of the machine, or the number of strokes it makes; whereas the stream which flows off by the cock is a constant quantity, and equal to that which the pump will supply when the machine moves with its intended velocity. When this is the case, the surface of water in the cistern will stand at the same height; but if the velocity is increased, the pump will raise more water into the cistern than the pipe and cock will carry off, and the surface rising, elevates the float, which, by its action to diminish the supply of power to the machine, will correct the acceleration which had taken place in its velocity. The opposite effect takes place if the velocity decreases, *viz.* that the supply to the cistern being diminished whilst the efflux is constant, the surface will sink, and the float descending, opens the valve or shuttle, and increases the supply of power to the machine until it regains the original velocity. The great advantage of this regulator is, that it can so readily be made to keep the machine steady at any velocity which may be required, and this by merely opening or closing the cock: thus, if it is opened to carry off a greater quantity, the surface will subside, and the float, by descending, opens a greater supply of power to the machine, and occasions it to move quicker; but this, though it raises more water by means of the pump, will not raise the surface of the water in the cistern to so great a height as it stood at before, because the efflux is now equal to the increased supply.

In all cases this regulator will cause the machine to work at such a rate, as to make the pump raise the same quantity of water as the cock emits, and its rate may be ascertained before it is put to work; for if the quantity of water which the cock will discharge in a minute, or other given space of time, is known, and the dimensions of the pump; then it may easily be calculated what number of strokes *per* minute the pump must make to raise an equal quantity of water. The sensibility of this regulator will be increased by making the cistern of a small size, because then any deviation from the intended rate of working will cause the greater elevation or depression of the surface, and a greater action on the float: and, for the same purpose, it is best to make the cistern gradually diminish in area, so as to be smaller both towards the top and at the bottom, than at the place where the surface is expected to stand when the machine moves with the proper velocity. By this means it will rise or fall more rapidly, in consequence of the diminished area of the cistern, when the alteration of velocity is considerable, and a greater correction is required, than when the alteration is only trifling. It is necessary that the pump should raise a constant stream of water into the cistern, both in the ascent and descent of its bucket: to do this, two pumps, acting alternately, may be used, or by a very simple contrivance a single pump may be made to effect the same; thus, upon the rod of the pump a cylinder of wood is fixed, which is of such a diameter, that its area is equal to half the area of the pump-barrel, and its

length being equal to the length thereof, its content will be equal to one-half of the barrel: this is fixed on such a part of the rod, that it will, by the rising and falling of the rod, be drawn up out of water as much as the rod and bucket moves: now, when the pump-bucket is drawn up, the rising of the cylinder above the surface of the water increases the capacity of the cistern one-half as much as the quantity of water which is thus drawn up into it, and the efflux of water by the cock being just equal to the other half, the surface will be stationary; and when the bucket descends, and no water is raised, the cylinder going down into the water diminishes the capacity of the cistern a quantity equal to the quantity of water which will flow off in the same time, and thus supplies the waste of water which flows off in the same time. A regulator of this kind may, in many cases, be formed from some part of the machine, without any additional apparatus: thus, the cold water-pump of a steam-engine will raise the necessary water into a cistern for the float to act in, and this float must be connected with the arm of the steam-valve. Also, in an engine for blowing a furnace, where it has a water-regulator (see *BLOWING*), the rise of the water in the external cistern may regulate the motion of the engine, the whole machine being of the same kind with the regulator we have described.

A regulator would be applied with great advantage to a machine which is used in the *Cotton MANUFACTURE* (see that article), for drawing a piece of cotton cloth regularly and slowly over a red-hot cylinder of iron by two rollers, from one of which it is wound to the other: now, if the men who turn these stop but for a moment the cloth is burnt through, but by a regulator it might be lifted off the hot iron the instant the motion was so far diminished as to endanger the firing of it.

The water-regulator is rendered more powerful by suspending the cistern from the end of a lever, like a scale-beam, the opposite end of which has a counterpoise sufficient to balance the weight of the cistern when the water in it stands at the intended height; but if the water increases in the cistern from the causes above described, the box will descend, and the motion of the lever will act upon the machine to make the regulation the same as the motion of the float: on the other hand, when the water in the cistern diminishes, the counterpoise will draw it up and give motion to the lever. The water from the pump is introduced to the cistern by a spout, and all the other parts have the same construction as we have described.

It is a defect of both the regulators we have above described, that they do not operate upon the machine until the alteration of velocity has actually taken place, although they immediately correct it. It would be desirable to have others which would make the correction before the evil takes place: for instance, in a wind-mill, which is more subject to irregularity than any other machine, a large vane may be suspended by a heavy pendulum, and opposed to the wind; now the force of the latter, when blowing regularly, will cause the pendulum to incline a certain quantity from the perpendicular; but if the wind increases or diminishes, it will incline more or less, and this motion may be communicated to the shuttle which regulates the feed of corn, so as to give more or less to the stones in proportion to the power of the wind for grinding it, thus adapting the resistance to the power; and if this should increase beyond all bounds, the same motion may be made to act upon the grip of the mill to check its acceleration effectually. In the same manner a water-wheel may have a float placed in the dam or head to act upon the shuttle whenever the surface thereof rises or falls above or

below

below the intended level, so as to apportion the supply to the fall, and keep the velocity uniform.

There is another kind of regulator sometimes used in machines to cause a sufficient resistance to the motion to prevent acceleration, such as a crane or lowering machine, which is to let down a heavy weight, a coal winding machine, &c. ; a very good one for these purposes is a vertical axis with pendulums, like the governor, but having a broad vane to meet the air instead of heavy balls, which indeed may be added also : this, when put in motion, will oppose a very great resistance to the acceleration, because the centrifugal force causing the vanes to recede from the centre, they must describe a larger circle in the air in proportion to the velocity, or, by collapsing, they make but little resistance when the velocity is small.

REGULO, a title given to the sons of the emperor of China.

REGULUS, MARCUS ATTILIUS, in *Biography*, a celebrated Roman general, was raised to the consulship the first time in the year 267 B. C., and, in conjunction with his colleague Libo, obtained the honour of a triumph on account of their success over the Salentines, from whom they took their capital Brundisium. During the first Punic war the Romans elected Regulus consul, together with Lucius Manlius Vulso, B. C. 256, and gave them orders to carry their arms into Africa. They sailed with a very powerful fleet, and in their voyage encountered a superior Carthaginian force, under Hanno and Hamilcar, which they totally defeated. After resitting in Sicily, and taking fresh troops aboard, the consuls sailed for the African coast, where they took possession of the town of Clupea. They next advanced towards Carthage, which city was thrown into the utmost consternation by this unexpected invasion ; and, after plundering the country almost to its gates, they returned to Clupea loaded with booty of all kinds. Very soon after this, orders arrived from Rome for the return of Manlius, leaving Regulus with part of the fleet and army to conduct the war in Africa. Regulus asked for his recall upon the following plea : he was possessed of a farm of seven acres, from which his family derived their subsistence, and being informed that his servants were carrying off his stock, he begged that he might return to save his family from starving. The plea was over-ruled, by an order that they should be maintained by the public during his absence upon the service of his country. He again advanced towards Carthage, crossed the river Bagrada (in passing which, according to the Roman historians, he was encountered by a monstrous serpent,) and laid siege to a town not far from the metropolis. Hamilcar attempted to relieve the place, but Regulus met him and gave him a very signal defeat. After this he took several towns, without any resistance. A revolt of the Numidians reduced the Carthaginians to still greater distress, so that it appears the enemy fought for peace. The terms, however, offered by Regulus were so unreasonable, that the senate of Carthage could not for a moment listen to them, and resolved upon a vigorous prosecution of hostilities. During the interval of negotiation a body of Greek mercenaries arrived at Carthage, commanded by Xantippus, a Spartan, by whom the Romans were completely defeated, with the loss of 30,000 men, besides 15,000 taken prisoners, among whom was Regulus himself, whom the Carthaginians brought in triumph into that city, which, but a few hours before, he had not only insulted, but, in his own mind, devoted to destruction. Hitherto, says the historian, Regulus had appeared only as a Roman commander, and not one of the most conspicuous ; the concluding scenes of his life are those

which entitle him to rank among the first of Roman patriots. The Carthaginians behaved to their other prisoners humanely, but Regulus they treated with all the barbarity which they could devise ; but, when the fortune of war appeared to turn against them, they began to use him with more lenity, in order that they might engage him to endeavour to obtain an accommodation. At their desire he went with their ambassadors to Rome, having first taken an oath that he would return to his prison, if the negotiation should not succeed. When he arrived at the gates of the city he refused to enter, being, as he said, a slave to the Carthaginians ; and when his wife and children came out to meet him, he viewed them as strangers, and declined their caresses. The senators assembled to give audience to the Carthaginian ambassadors, pressed him to take his seat among them, but he refused, till commanded by his masters to accept it. When he was called on for his opinion, he spoke strongly both against granting the Carthaginians peace, and exchanging himself and the other Roman captives for the prisoners of importance whom they had taken from that nation. Though convinced by his arguments, the senators were unwilling to send back so noble a citizen, and a subterfuge was suggested to him by which he might be released from his oath, but he instantly rejected the base suggestion, and declared his resolution to return to Carthage in the face of the cruel punishment that he knew awaited him. Acting upon the idea that he was still a slave, he took no leave of his family, but, with an unmoved countenance, made his way in silence through the crowds of his admiring countrymen. The Carthaginians were told that their offers of peace were not only rejected at Rome, but chiefly so through the means of Regulus, whom now they resolved to punish in the severest manner possible. For some days he was exposed to the rays of a meridian sun, and afterwards confined in a barrel, whose sides were every where filled with large iron spikes, till he died in the greatest agonies. His sufferings were heard of at Rome, and the senate permitted his widow to inflict whatever punishment she pleased on some of the most illustrious captives of Carthage, and she took a severe revenge, till at last the senate interposed, and put a stop to the barbarity of her punishments. Regulus perished in the year B. C. 251. Univ. Hist.

REGULUS, *Petty King*, in our *Ancient Customs*, is a term frequently used, in the Saxon councils, for comes or count.

Hence *sub-regulus* was also used for a vice-comes or viscount : though in many places the two seem used indifferently for the same dignity. Thus in the archives of the cathedral of Worcester, Uthredus sometimes styles himself *regulus*, and sometimes *sub-regulus*, of the city of Worcester.

But in other places we find a distinction : "Offa, rex Merciorum ; Uthredus, *regulus* ; Aldredus, *sub-regulus*, &c."

REGULUS, *Konig*, Germ., in *Chemistry*, denotes, in its most extensive sense, a metal in the proper metallic state. The term is now little used, though the old chemists chiefly employed it as a distinctive appellation in those cases where a metal and one of its ores happened to be called by the same name. Thus, the grey sulphuret of antimony was not known by the name of antimony long before it was suspected to contain a peculiar metal ; when this discovery took place, the metal was called *regulus* of antimony, in order to distinguish it from the ore from which it was procured. For the same reason, the metals arsenic and cobalt were denominated the *reguli* of arsenic and cobalt.

REGULUS of *Antimony*. See ANTIMONY.

REGULUS, *Martial, of Antimony*. See ANTIMONY.

REGULUS of *Arsenic*. See ARSENIC.

REGULUS of *Cobalt*. See COBALT.

REGULUS, in *Astronomy*, is a star of the first magnitude, in the constellation Leo; called also, from its situation, *Cor Leonis*, or the *Lion's Heart*; by the Arabs, *Alhabor*; and by the Chaldeans, *Kalbeceed*, or *Kalbeceid*; from an opinion of its influencing the affairs of the heavens; as is observed by Theon. See LEO.

REGULUS, in *Ornithology*, a species of *Falco*; which see. — Also, a species of *Motacilla*; which see. — See also WREN.

REGUSSE, in *Geography*, a town of France, in the department of the Var; 9 miles N.E. of Barjols.

REGYA, a river of Africa, which runs into the Mediterranean; 16 miles E. of Algiers.

REHABERE *facias seisinam*, quando vicecomes liberavit seisinam de majore parte, *quam deberet*, in *Law*, a writ judicial; of which there is another of the same name and nature. (Reg. Jud. 13, 51, 54.) It lay when the sheriff in the *Habere facias seisinam* had delivered more than he ought.

REHABILITATION, REHABILITATIO, in the *Civil and Canon Law*, an action by which a prince or pope, by dispensation or letters patent, restores a delinquent to the condition he was in before his delinquency. See DEGRADATION.

The king alone can rehabilitate an officer, noted, condemned, and degraded; or a gentleman who has derogated from his rank.

The pope alone pretends to rehabilitate, *i. e.* to render capable of benefices and orders, such as had fallen into heresy or other irregularities.

In Romish countries, an ecclesiastic who assists at the execution of a sentence of death, is to be rehabilitated by an absolution, called *a sevis*.

By the *rehabilitation* of a convict in the Code Napoleon, or French criminal jurisprudence, is understood his restoration to all the rights and privileges which he had forfeited by being subjected to a painful or infamous punishment. He cannot demand it till five years have elapsed since the execution of his sentence, during the whole of which time he must have resided in the same *arrondissement*; or unless he has been domiciled during two complete years in the territory of the municipality to which the demand is addressed. It must also be supported by testimonials of his good conduct from the municipal authorities. The criminal court receives the demand, and pronounces on it at the end of three months: if their judgment be unfavourable, the application may be renewed at the end of five years, with the same advantage; but if the party rehabilitated into society should offend again, he becomes incapacitated for ever.

REHBURG, in *Geography*, a town of Westphalia, in the principality of Calenberg; 18 miles W.N.W. of Hannover.

REHEARING, in the *Court of Chancery*, is a process to which either party, that thinks himself aggrieved, may have recourse, before the execution of a final decree. Every petition for a rehearing must be signed by two counsel of character, certifying that they apprehend the cause is proper to be reheard. And upon the rehearing, all the evidence taken in the cause, whether read before or not, is now admitted to be read; because it is the decree of the chancellor himself, who only now sits to hear reasons why it should not be enrolled and perfected; at which time, all omissions of either evidence or argument may be supplied. But after the decree is once signed by the chancellor, and enrolled, it can-

not be reheard or rectified, except by bill of review, or by appeal to the house of lords.

REHEARSAL, in *Music* and the *Drama*, an essay or experiment of some composition, which is made in private, previous to the representation or performance of it in public; to habituate the actors or performers, and make them more ready and perfect in their parts.

REHOBOTH, in *Geography*, a post-town of America, in Bristol county, Massachusetts, on a branch of Providence river, a few miles from Providence, in Rhode island, 40 miles southerly from Boston. It was called "Seconnet" by the Indians; incorporated in 1645, and contains 4866 inhabitants.

REHUT, a town of Hindoostan, in the circle of Gohud; 20 miles S.S.W. of Gwalior.

REI *Domestica Domesticus*. See DOMESTICUS.

REICH, in *Geography*, a town of Austria; 7 miles N.W. of Schwaneftadt.

REICHARDT, JOHN FREDERIC, in *Biography*, chapel-master to Frederic II. king of Prussia, at Berlin, was born at Königsberg, in Prussia, in 1751, and studied under the organist of the principal church. Richter taught him the harpsichord, and formed his taste. He likewise practised the violin, and was powerful upon that instrument, particularly in double stops. With these talents he travelled in 1771, distinguishing himself in Upper and Lower Saxony, Dresden, Leipzig, Brunswick, Hamburg, and Berlin; where he was appointed by the king, in 1775, chapel-master, in the station which Graun had formerly illustrated.

The first composition which he produced in his new office, was a prologue to Graun's opera of "Angelica e Medoro," which he set on occasion of a visit to the king of Prussia by the grand duke of Russia, in 1776; in which prologue he composed the famous air "Nell' orror d'Atra Foresta," for Mad. Mara.

In 1783 he went to Paris, and gave proofs of his abilities at the concert spirituel; and in 1784, he was present at the commemoration of Handel in London. He married the daughter of Francis Benda, born the same year as himself, an excellent singer.

REICHELIA, in *Botany*, Schreb. Gen. 200. (Sagonea; Aubl. Guian. t. 111. Juss. 134. Lamarck Illustr. t. 212.) Reduced by its author, on the suggestion of Swartz, to *Hydrolea*; Schreb. 826. There have been two botanists of the name of Reichel; but Schreber, most probably, had principally in view George Christian Reichel, professor of medicine at Leipzig, who published a dissertation on the Spiral Vessels of Plants, and died in 1771, at the age of 44.

REICHELSBERG, in *Geography*, a lordship of Germany, in the circle of Franconia, deriving its name from a mountain citadel, near the town of Aube, in the duchy of Wurzburg.

REICHELSBURG, a town of the duchy of Wurzburg; 20 miles S.E. of Wurzburg.

REICHELSDORF, a town of Bavaria, in the territory of Nuremberg; 7 miles S. of Nuremberg.

REICHELSHEIM, a town of the duchy of Wurzburg; 4 miles W. of Arnheim.—Also, a town of the principality of Nassau Weilburg, insulated in the bishopric of Fulda; 30 miles S. of Marburg.

REICHELSWAND, a town of Bavaria, in the territory of Nuremberg; 3 miles E. of Lauf.

REICHENAU, an island in the lake of Constance, about two miles long, and abounding with vines and other fruit

fruit trees, with a celebrated abbey, and the villages of Upper and Lower Zell.—Also, a town of Bohemia, in the circle of Chrudim; 9 miles W.N.W. of Politzka.—Also, a town of Austria; 5 miles S.W. of Freytsadt.—Also, a town of Saxony, in the Vogtland, near Pawfa.—Also, a town of the Helvetic republic, at the union of the two branches of the Rhine; 6 miles S.W. of Coire.—Also, a town of Bohemia, in the circle of Bechin; 6 miles E. of Rosenbergl.—Also, a town of Bohemia, called “New Reichenau,” in the circle of Bechin; 8 miles E.S.E. of Pilgram.—Also, a town of Prussia, in the province of Oberland; 8 miles S.E. of Osterrod.—Also, a town of Prussia, on the Ossa; 22 miles E.N.E. of Culm.

REICHENBACH, a town of Saxony, in the Vogtland, containing about 700 houses, two churches, and a Latin school. The inhabitants are chiefly clothiers, and dealers in cloth. Their method of dyeing is held in high estimation, the most beautiful scarlet in the whole electorate being made at this place; 10 miles S.W. of Zwickau. N. lat. $50^{\circ} 31'$. E. long. $12^{\circ} 16'$.—Also, a town of Silesia, in the principality of Schweidnitz, containing two churches and an hospital. The town has some considerable manufactures of linen, canvas, and fustian; 9 miles N. of Schweidnitz. N. lat. $50^{\circ} 35'$. E. long. $16^{\circ} 35'$.—Also, a town of France, in the department of the Sarre; 8 miles S. of Lautereck.—Also, a town of Lusatia; 4 miles S.W. of Camenz.—Also, a town of Prussia, in the province of Oberland; 7 miles S.S.W. of Holland.—Also, a town of Germany, in the county of Henneberg; 3 miles N. of Smalkalden.—Also, a town of Germany, in the principality of Culmbach; 12 miles E.N.E. of Neustadt.—Also, a town of Germany, in the margraviate of Anspach; 2 miles N.W. of Schwabach.

REICHENBERG, a mountain of Swabia; 6 miles N.W. of Huißingen.—Also, a town of Bohemia, in the circle of Boleflaw. Twenty thousand pieces of cloth are supposed to have been made in this town in one year; 25 miles N.N.E. of Jung-Buntzlau.—Also, a town of Prussia, in the province of Ermeland; 3 miles S.W. of Heilsberg.—Also, a town and castle of Westphalia, in the county of Catzenelnbogen; 5 miles E. of St. Goar.

REICHENBURG, a town of the duchy of Stiria; 12 miles S.S.E. of Cilly.

REICHENECK, a town of the duchy of Stiria; 5 miles E.S.E. of Cilly.

REICHENFELS, a town with a castle in Saxony, in the principality of Reussen; 8 miles N.W. of Greitz.—Also, a town of the duchy of Carinthia; 24 miles N.E. of Clagenfurt.

REICHENHALL, a town of Bavaria, on the Sala, with a rich salt spring, the water of which is partly boiled here, and partly, by means of a large wheel 36 feet in diameter, thrown up to the higher parts of a lofty house, and thence conveyed by means of leaden pipes to the distance of 12 miles, over mountains, towards Traunstein, and there boiled, on account of the convenience of wood, and also of exportation. An aqueduct of squared flints, two miles long and five feet broad, with an arched roof, was formed some centuries ago, for conveying water to turn the wheels and other engines, and to carry off any superfluous salt water. This aqueduct, after running to a depth of 12 fathoms under the town, and from thence under the gardens and fields, at last discharges its water in a strong torrent. The current of the water is so strong, that a boat with torches may sail from one end to the other in a quarter of an hour. In the aqueduct are five apertures in the form of towers, and through some of these a person may speak from the ram-

parts of the town with those who sail upon the canal; 9 miles S.W. of Salzburg. N. lat. $47^{\circ} 40'$. E. long. $12^{\circ} 50'$.

REICHENSTAIN, a town of Aultria; 19 miles N.E. of Steyregg.

REICHENSTEIN, a town of Silesia, belonging to the principality of Bieg, but insulated in that of Mautterberg; 16 miles W. of Neisse. N. lat. $50^{\circ} 15'$. E. long. $16^{\circ} 40'$.—Also, a town of France, in the department of the Roer; 21 miles S. of Juliers.

REICHENSTEIN, *Unter*, a town of Bohemia, in the circle of Prachatitz; 3 miles W.S.W. of Berg Reichenstein.

REICHENTAL, a town of Aultria; 3 miles E. of Haderdorf.

REICHENWALT, or RIECHERSWALDE, a town of Prussia, in Oberland; 4 miles N.W. of Liebstat.

REICHERSDORF, a town of Transylvania; 4 miles E. of Medies.

REICHMANSHAUSEN, a town of the duchy of Wurzburg; 10 miles E.N.E. of Schweinfurt.

REICHNAW, a town of Bohemia, in the circle of Konigingratz; 17 miles E.S.E. of Konigingratz.—Also, a town of Lusatia; 6 miles W. of Gorlitz.

REICHNICH, a town of the duchy of Stiria; 6 miles N.E. of Windisch Gratz.

REICHHOLDGRUN, a town of Germany, in the principality of Culmbach; 2 miles S. of Kirch Lamitz.

REICHSHOFEN, a town of France, in the department of the Lower Rhine; 9 miles N. of Haguenau.

REICHSTHABER, in *Commerce*. See RIX-DOLLAR.

REICHTHAL, in *Geography*, a town of Silesia, in the principality of Breslau; 32 miles S. of Breslau. N. lat. $51^{\circ} 9'$. E. long. $17^{\circ} 52'$.

REID, THOMAS, in *Biography*, an eminent divine and moralist, was born at Strachan, in Kincardineshire, of which parish his father was minister, in the year 1710. The elements of learning he received at the parish school of Kincardine, after which he was sent to a classical school at Aberdeen; and so rapid was his progress in his studies, that about the age of thirteen he was found fully qualified for the university, and entered as a student in Marischal college. Here he distinguished himself by his proficiency in the various branches of learning taught during the usual course of four years, particularly in mathematics. At this period he probably took his degree of M.A., and afterwards commenced the study of theology, and in due time was licensed as a preacher. He was soon appointed librarian to the university, and became intimately acquainted with Mr. John Stewart, the professor of mathematics. This connection strengthened and confirmed his predilection for mathematical studies. Occasionally he read lectures for his friend, in which he discovered a happy faculty of making every thing intelligible to the students, which he clearly apprehended himself. In 1736 Mr. Reid resigned his situation of librarian, and accompanied Mr. Stewart on an excursion into England, and became acquainted with many illustrious characters in London, at Oxford, and at Cambridge. In the following year, Mr. Reid was presented by the King's college of Aberdeen to the living of New Machar; but his entrance into the functions of his office was very unpropitious. His unwearied attention, however, to the duties of his office, the mildness and forbearance of his temper, and the active spirit of his humanity, soon overcame all their prejudices; and not many years afterwards, when he was called to a different situation, the same persons, who had taken a share in the outrages against him, followed him, on his departure, with their prayers and tears.

tears. "We fought," said some of them, "against Mr. Reid, when he came; and would have fought for him, when he went away."

The greater part of his residence at New Machar was devoted to the most intense study; and by way of amusement, he had recourse to gardening and botany, of which he was extremely fond, even in old age. In the year 1748 he published a paper in the Transactions of the Royal Society of London, entitled "An Essay on Quantity, occasioned by reading a Treatise, in which simple and compound Ratios are applied to Virtue and Merit." The treatise here referred to was Dr. Hutcheson's "Inquiry into the Origin of our Ideas of Beauty and Virtue."

The professors of King's college, Aberdeen, in the year 1752, appointed Dr. Reid to be professor of philosophy: the choice originated wholly from the high opinion they were led to entertain of his talents and erudition. It is not known what particular plan he pursued in the course of his lectures; but his department comprehended mathematics, and physics, logic, and ethics. Soon after his removal to this situation, he projected, in conjunction with his friend, Dr. John Gregory, a literary society, which subsisted many years, and which, it is believed, had considerable effect in exciting and directing that spirit of philosophical research, which has since so particularly distinguished the north of Scotland. The writings of Reid, Gregory, Campbell, Beattie, and Gerard, evince the numerous advantages which the members derived from this institution, as they were in the habit of bringing such works as they intended for publication to the test of friendly criticism. Among these the most original was that of our author, published in 1764, entitled "An Inquiry into the Human Mind, on the Principles of Common Sense;" intended to refute the philosophy of Locke and Hartley, by denying the connection which they supposed to subsist between the several phenomena, powers, and operations of the mind; and accounting for the foundation of all human knowledge on a system of instinctive principles. About the time when this "Inquiry" made its appearance, the author received from the college of Aberdeen the degree of doctor of divinity; and by the university of Glasgow he was invited to the professorship of moral philosophy. On the duties attached to this office he entered in 1764; and he was enabled, by means of a handsome income, to concentrate all his attention to his favourite pursuits, which had hitherto been distracted by the miscellaneous nature of his academical engagements. The researches of Dr. Reid concerning the human mind, were extended and methodized in a course, which employed five hours every week, during six months in every year. The substance of these lectures was afterwards given to the world, in a more improved form, in the last of his publications. In the year 1773 appeared, in the form of an appendix to the third volume of Lord Kames' "Sketches of the History of Man," a brief account of Aristotle's logic, with remarks by Dr. Reid. In the year 1781 Dr. Reid withdrew from his public labours, but he was not inactive: his subsequent works afford proof of the assiduity with which he availed himself of his literary leisure. In 1785 he published his "Essays on the Intellectual Powers of Man;" and in 1788, those "On the Active Powers." These volumes complete the system of philosophy, begun in his "Inquiry" many years before.

Notwithstanding his advanced age, Dr. Reid continued to prosecute his studies with unabated ardour and activity. The modern improvements in chemistry attracted his particular notice, and he applied himself with his accustomed diligence to the study of its theories and nomenclature. He

amused himself also, at times, in preparing for a philosophical society, of which he was a member, short essays on particular topics, which happened to interest his curiosity, and on which he thought he might derive or afford useful hints in the course of friendly discussion. His last essay appears to have been written in the 86th year of his age, and was read by the author to his associates but a short time previously to his death. In the month of September 1796, he was seized with a violent disorder, with which he for some time maintained a severe struggle; but which, together with some paralytic attacks, put an end to his useful life on the 7th of October, in the 87th year of his age. In point of bodily constitution, few men have been more indebted to nature than Dr. Reid. His form was vigorous and athletic, and his countenance was strongly expressive of deep and collected thought; but when brightened up by the face of a friend, what chiefly caught the attention was a look of good will and of kindness. The most prominent features of his character were intrepid and inflexible rectitude, a pure and devoted attachment to truth, and an entire command over his passions. In private life, no man ever maintained, more eminently or more uniformly, the dignity of philosophy; combining with the most amiable modesty and gentleness, the noblest spirit of independence. As a public teacher, he was distinguished by unwearied assiduity in inculcating principles, which he conceived to be of essential importance to human happiness. In his elocution and mode of instruction, there was nothing peculiarly attractive. Such, however, were the simplicity and perspicuity of his style; such the gravity and authority of his character, that he was always listened to with profound respect, and, in his latter years, with a veneration, which age added to great wisdom always inspires. Stewart's Life of Reid.

REIDEN, in *Geography*, a town of Switzerland, in the canton of Lucerne; 18 miles N.N.W. of Lucerne.

REJECTIO, a word used by medical authors for the casting any thing up preternaturally by the mouth, whether it be by vomiting or by spitting.

REIFF, in *Geography*. See RIVA.

REIFFERSCHÉID, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Prum. The place contains 311, and the canton 3542 inhabitants, in 45 communes.—AISO, a town of France, in the department of the Rhine and Moselle, capital of a county in the archbishopric of Cologne; 42 miles W. of Coblenz. N. lat. 50° 33'. E. long. 6° 27'.

REIFFLING, a town of the duchy of Stiria, on the river Enns; 28 miles N.W. of Pruck.

REIFFNITZ, a town of Middle Carniola; 4 miles N. W. of Gottschee.

REIFTENBERG, a town of Austria; 59 miles S.E. of Goritz.

REIGELSBERG, a lordship of the duchy of Wurzburg.

REIGNAC, a town of France, in the department of the Gironde; 9 miles N.E. of Blaye.

REIGNIER, a town of France, in the department of the Léman, and chief place of a canton, in the district of Geneva. The place contains 1280, and the canton 9046 inhabitants, on a territory of 102½ kilometres, in 14 communes.

REIGNING WINDS, in *Meteorology*, are those winds which usually prevail in any particular coast or region, the knowledge of which is essentially necessary to every pilot, who is charged with the navigation in those seas.

REIKENES, in *Geography*, a cape on the S. coast of Iceland. N. lat. 63° 43'.

REIKEVIG,

REIKEVIG, a sea-port town of Iceland, consisting of about 60 or 70 houses, standing in two rows of nearly equal length, at right angles to each other, the high street being encumbered with rock. Among the rocks, which on every side surround the town, are scattered wretched hovels, a little raised above the level of the ground. The adjacent country much resembles the summit of some of the highest mountains in Scotland, being composed of fragments of rocks, and presenting only a few patches of alpine vegetation. Almost all the houses of Reikevig are of Norwegian construction, and inhabited by Danes. The women of this town are principally employed in the operation of drying fish. On the little island of Akarve, near this town, are bred eider ducks in great numbers. About six miles to the south of Reikevig is an immense bed of lava, extending a length of 25 miles, and having its black and desolate surface broken into masses and fragments, which render it difficult and dangerous to traverse it, especially where quantities of the "trichostomum" conceal the hollow parts from view. The breadth of this remarkable current varies from two to ten miles; and its hideously shattered aspect is supposed to have resulted from the expansive force of elastic fluids which escaped during the cooling of the lava. Most of the produce of the Icelanders is brought to Reikevig; and the inhabitants of the interior of the country take back, in exchange for their tallow and skins, the dried heads of the cod-fish, and such fish as are injured by the rain and not fit for exportation. These form the principal article of their food, and are eaten raw, with the addition of butter, &c. Bishop Videlinus in this place has a library of 5 or 600 volumes. The author of the work now cited states the height of Hecla at about 5000 feet, and the population of Iceland at about 48,000 persons, who, from the rigour and instability of their climate, can never rely on their native produce even for the necessary articles of subsistence. The principal articles of export are dried fish, (especially cod of a superior quality,) mutton, lamb, beef, butter, tallow, train-oil, coarse woollen cloth, the skins of sheep, lambs and foxes, eider-down and feathers; and their chief importations are timber, fishing tackle, various implements of tin, tobacco, bread, spirituous liquors, salt, linen, &c. A large proportion of their food consists of fish, butter, and various preparations of milk. Hooker's Journal of a Tour in Iceland in 1809.

REILLANE, a town of France, in the department of the Lower Alps; 7 miles S. of Forcalquier.

REIMBURSEMENT, in *Commerce*, the act of repaying or returning what monies a person had received, by way of advance, &c. or what another had disbursed or paid for him. A person who gives a bill of exchange in payment, is to reimburse it, if it come to be protested, for want of being accepted or paid.

REIMBURSING is also used for paying the price a commodity costs its owner.

REIMS, or **RHEIMS**, in *Geography*, one of the most ancient and celebrated cities of France, and principal place of a district, in the department of the Marne, seated on the Vesle. Before the revolution this city was the see of an archbishop, who was the first duke and peer of France, and always crowned the king. In this place was the abbey of the Benedictines of St. Remy, the noblest of that order in the kingdom of France; and on the altar of its church, under which St. Remigius was buried, was kept the holy vial, which, as tradition reports, was, in the year 496, at the baptism of Clovis by bishop Remigius, brought from heaven by a dove in deference to the prayer of that saint; the crowd obstructing his passage to the font with the usual

oil. The university of Reims was founded in 1547, and in the following year authorized by the parliament of Paris. This city contains 30,295 inhabitants, in the three parts into which it is divided, and it has three corresponding cantons, the first containing 12,140, the second 10,107, and the third 10,874, in three, four, and five communes respectively, on a territory of 117½ kilometres. Rheims carries on a considerable trade in wine, woollen and silk stuffs, and gingerbread. It has several remains of Roman antiquities, particularly the three gates of the city, which still bear the names of as many Pagan deities, viz. the Sun, Mars, and Ceres. It was taken by the English in the reign of Henry V. N. lat. 49° 15'. E. long. 4° 6'.

REIN, a town of the duchy of Stiria; 9 miles N.W. of Gratz.—Also, a town of the same duchy, on the river Save; 20 miles E. of Cilley.

REIN-Deer, in *Zoology*. See *CERVUS Tarandus*.

REINDORFF, in *Geography*, a town of Bavaria; 4 miles S.S.W. of Bamberg.

REINECCIUS, **REINER**, in *Biography*, a learned German, who flourished in the 16th century, was a disciple of Melancthon, and taught the belles lettres in the universities of Frankfort and Helmstadt till his death, in 1595. He is known to the learned world by several works on history and genealogy, in which he was profoundly versed. His chief publications are, "Syntagma de Familiis Monarchiarum trium priorum," 1574; "Familie Regum Judæorum;" "Chronicon Hierosolymitanum;" "Historia Orientalis;" "Historia Julia," three vols. folio; "Methodus Legendi Historiam."

REINECK, in *Geography*, a town of France, in the department of the Rhine and Moselle, late capital of a burgraviate, deriving its name from it, and situated between the duchy of Juliers and electorate of Cologne, on the borders of the Rhine; 14 miles N.N.W. of Coblenz.

REINEN. See **RHEINE**.

REINERTZ, a town of Silesia, in the comté of Glatz, on the borders of Bohemia; famous for its manufactures of beautiful cloth and plush, and excellent paper, equal to the best in Holland; 11 miles W. of Glatz. N. lat. 50° 14'. E. long. 16° 10'.

REINFELDT, a town of Prussia, in the province of Pomerelia; 12 miles S.W. of Dantzic.

REINFORCE, in *Gunnery*, is that part of a gun next to the breech, which is made stronger, to resist the force of the powder. There are generally two reinforces in each piece, called the first and second reinforce: the second is somewhat smaller than the first, upon the supposition that when the powder is inflamed and occupies a greater space, its force is diminished, which is very absurd. See **CANNON**.

REINFORCE Rings of a cannon, are flat mouldings like iron hoops, placed at the breech-end of the first and second reinforce, projecting beyond the rest of the metal about one-fourth of an inch. See **CANNON**.

REINFORCEMENT, in *War*, a supply, or new provision of men, arms, ammunition, &c.

REINGUS, in *Geography*, a town of Austria; 12 miles N.N.W. of Waidhoven.

REINHARTSBRUNN, a town of Germany, in the principality of Gotha; 10 miles S.S.W. of Gotha.

REINHARTZ, a town of Saxony; two miles W. of Schmiedelberg.

REINHEIM, a town of the principality of Hesse Darmstadt; 5 miles S.E. of Darmstadt.

REINHOLD, **ERASMUS**, in *Biography*, an eminent German mathematician, was born at Salsfeldt, in Thuringia, a province in Upper Saxony, in the year 1511. He was educated

educated at the university of Wittemberg, where his genius chiefly inclined him to the study of the mathematics, which he cultivated with great success. He afterwards became a professor of those sciences in the same university, and acquired very high reputation, not only by his lectures, but by the learned and useful writings which he communicated to the public. Of these, which are very numerous, we may mention "Theoriae Novae Planetarum G. Purbachii," augmented and illustrated with diagrams and scholia. "Ptolemy's Almagest, with a Latin Version, and Scholia." In 1551 he published "Prutenicæ Tabulæ Cœlestium Motuum," which were several times reprinted. In carrying on this work, which cost seven years' labour, he was encouraged by the munificence of Albert, duke of Prussia. They were constructed by him from a comparison of the observations of Copernicus with those of Ptolemy and Hipparchus, and he has fully explained the use of them in a great number of precepts and canons, forming a complete introduction to practical astronomy. Reinhold also made many astronomical observations, but he never had any better instrument than a wooden quadrant. The result of these observations were shewn to Tycho Brahe after the death of Reinhold, who expressed his surprize that so great and meritorious a cultivator of astronomical science was not furnished with better instruments. Reinhold died in 1553, when only in the 42d year of his age, pronouncing the following verse a short time before he expired.

"Vixi, et quem dederas cursum mihi, Christe, peregi."

He had a son of the same name, eminent as a mathematician and physician, who published a small work in the German language "On Subterranean Geometry;" also a tract concerning the new star which appeared in Cassiopeia in 1572.

REINISCHDORF, in *Geography*, a town of Silesia, in the principality of Neisse; 5 miles N. of Neisse.

REINS, in *Anatomy*, the kidneys. See KIDNEY and RENES.

The word, according to Varro, is formed from the Greek, $\rho\epsilon\iota\nu$, *quasi rivi obsceni humoris ab iis oriantur*.—The Greeks call the rein $\nu\epsilon\phi\alpha\sigma$, from the verb $\nu\epsilon\phi\epsilon\iota\nu$, *to rain, snow, &c.*

In the manege they say, a horse should have *double reins*; that is, he should have them a little more elevated on each side of the back-bone, than upon it; so that, passing your hand along it, you find it large, well-furnished, and double, by the hollow that goes all along the back-bone. The back should be firm and not hollow, or bending from the withers to the croup, but straight.

REINS, of a bridle, also denote two straps of leather meeting in the bridle-hand of the horseman, in order to make the bit bear, and keep the horse under subjection. See BRIDLE.

It is also a name given by the duke of Newcastle to two straps or ropes of a cavesson, which he ordered to be made fast to the girths, or the pommel of the saddle, with intent that the rider should pull them with his hand, in order to bend and supple the neck of the horse.

REIN, *Falſe*, is a lath of leather, passed sometimes through the banquet, to bend the horse's neck, which is disapproved of by the duke of Newcastle, because it slackens the curb, and makes the bit no more than a trench that has no curb.

REINS, in *Rural Economy*, the long thongs or strips of leather, or other materials, by which horses or other animals are directed in carriages or teams. These reins are much used in some counties, as Norfolk and Suffolk, in directing the plough-teams, in order to save the expence of another

person, the ploughman directing them in this way himself the driver being by this means dispensed with.

REINS, *Check*, a term signifying the same thing as a fort of rein, and which is made use of in particular districts, in checking and directing the animals.

REINS, *Whip*, a term used to signify a sort of hempen rein, employed for directing the team in ploughing in some districts, so called in consequence of being used instead of whips.

REINS of a Vault. See VAULT.

REINSBERG, or RIINSBERG, in *Geography*, a town of Brandenburg, in the Middle Mark; 10 miles N.N.E. of New Ruppin. N. lat. 53° 4'. E. long. 12° 58'.

REINSCHNICK, DER, a mountain of Stiria; 12 miles S.E. of Landferg.

REINSDORF, a town of Saxony, in the circle of Erzgebirg; two miles E.S.E. of Zwickau.

REINSPURG, a town of Bavaria, in the territory of Rothenburg; six miles S.S.W. of Rothenburg.

REINSTATING, the restoring of a person or thing to its former state or condition, from whence it had been disturbed or displaced. See REHABILITATION.

REINSTEIN, in *Geography*. See REGENSTEIN.

REINSURANCE, or RE-ASSURANCE, in *Commerce*, a contract by which a first insurer relieves himself from the risks which he has undertaken, and devotes them upon other under-writers, called re-insurers, or re-assurers. When a policy of insurance has been once signed, the under-writers are bound by the terms of it; nor can they be released from their contract without the consent of the insured. But if an under-writer repent of what he has done; if he be afraid to encounter the risk which he has engaged to run; or if he find that he has incautiously engaged himself to a greater amount than he may be able to discharge, he may shift it, or part of it, from himself to other insurers, by causing a re-insurance to be made on the same risk, upon the best terms in his power, and the new insurers will be responsible to him in case of loss, to the amount of the re-insurance. But in such case, the new insurers are responsible to the original under-writer only, and not to the original insured, who can have no remedy against him, in case of loss, even though the original insurer become insolvent; because there is no privity of contract between the original insured and the re-insurer. If, therefore, the original insurer fail, so that the original insured receive only a dividend, however small, the re-insurer can gain nothing by this, but must pay the full amount of the loss to the original insurer. Such is the law on this subject, in most of the commercial states of Europe. But in this country it was found, about the time when the statute 19 Geo. II. c. 17. was made, that this mode of insurance, though perfectly reasonable, when confined to its proper object, had been perverted from its original use, and was employed as a mode of speculating in the rise and fall of premiums; and the legislature foreseeing that it might be used as a colour for wager policies, and a means of evading the provisions of that act, declares (sect. 4.) "that it shall not be lawful to make re-insurance, unless the insurer shall be insolvent, become bankrupt, or die; in either of which cases, such insurer, his executors, administrators or assigns, may make re-insurance to the amount of the sum before by him insured; provided it be expressed in the policy to be a re-insurance." This clause, having no words to confine its operation to ships belonging to British subjects, like the first clause of the act restraining insurances, *interest or no interest*, extends to re-insurances made in England in foreign ships, even when they are insured abroad. This has been so determined; though it is observable that the following case, in which

which that question was made, was not the species of re-insurance above described, and to which only the statute refers, but a *second insurance*, effected on account of the *original insured*.

That was the case of an insurance made in London, on a French vessel, which had before been insured at Marseilles for the same sum, by an insurer there, who, at the time of subscribing the second policy, was living and solvent, and who, in fact, afterwards paid the sum insured by him. Upon this case the court determined that the latter policy was void by the words of the act; for though the first clause of the act which prohibits insurances, 'interest or no interest,' is confined to insurances on British ships, yet the fourth section being general, and without any such restrictive clause, every re-insurance in this country, either by British subjects, or foreigners, on British or foreign ships, is declared void by the statute, unless the first insurer be insolvent, become bankrupt, or die.

There are two other kinds of re-insurance; the one where the insured insures the solvency of the insurers; the other, where he makes a new insurance, in consequence of the insolvency of an insurer during the continuance of the risk.

The insurance of the solvency of an insurer is permitted and practised in some foreign countries; but it seems never to have been in use among us; not, perhaps, as has been supposed, because the solvency of an under-writer is not an insurable interest, or that such an insurance would be deemed a wager; but, more probably, because the insolvency of an insurer seldom happens in England; besides, a *double insurance* would better answer the end proposed.

If France, if an insurer fail during the continuance of the risk, the insured may insist on the dissolution of the contract, unless the creditors of the insolvent insurer, in order to entitle themselves to receive the premium, (which is rarely paid in that country till after the risk is ended,) will give security for the payment of the sum insured, in case of loss. At Marseilles, (for in France different practices prevail in different provinces,) the insured, in such case, sues the insolvent insurer, till he obtains a sentence, authorizing him to re-insure at the expence of the insolvent, which he may deduct from the stipulated premium, if it be not paid, and if this be insufficient, then out of the effects of the insolvent.

Double insurance is where the insured makes two insurances on the same risk, and the same interest; and it differs from a re-insurance in this, that it is made by the *insured*, in order that he may be entitled to receive a double satisfaction, in case of loss; whereas, a re-insurance is made by a former insurer, his executors or assigns, to protect himself and his estate from a risk to which they were liable by the first insurance. A re-insurance, except in the cases permitted by the stat. 19 Geo. II. c. 37. § 4, is absolutely void; but a double insurance, though it be made with a view to a double satisfaction in case of loss, and is therefore in the nature of a wager, is not void by the law of England. The two policies are considered as making but *one insurance*. They are good to the extent of the value of the effects put in risk: but the insured shall not be permitted to recover a double satisfaction. He may sue the under-writers on both the policies, but he can only recover the real amount of his loss, to which all the under-writers shall contribute in proportion to their several subscriptions. And therefore, if he should content himself with suing only on one of the policies, the under-writers on that policy may recover a rateable contribution from those on the other.

In consequence of the determination of lord Mansfield, in 1763, it has been agreed to be the course of practice, that,

upon a double insurance, though the insured is not entitled to two satisfactions, yet, that in an action upon the first policy, he may recover the whole sum insured, and may leave the defendants therein to recover a rateable satisfaction from the other insurers. Formerly, in the case of an *over-insurance*, that is, where, in a single policy, the sums subscribed amount to much more than the value of the effects insured, the first under-writers on the policy were holden to be answerable to the extent of the loss, and the subsequent ones discharged. Although only a single satisfaction can be recovered on a double insurance by the same person, yet different persons may insure the same thing, and each recover the full value of the thing insured. To enable the defendant, in an action on a policy, to discover whether there be a double insurance, he may, by the authority of the statute 19 Geo. II. c. 37. § 6, call upon the plaintiff to declare in writing, what sums he has insured in the whole, and how much he has borrowed on bottomry or respondentia. Marshal's Treatise on the Law of Insurance, vol. i. ch. 4. § 4.

REINTAL, in *Geography*, a town of Austria; four miles E.S.E. of Feldsberg.

REINTEGRATION. See REDINTEGRATION.

REJOICING FIRE, in *Military Affairs*, is used on obtaining a victory, or in celebrating some public festival: of this there are two sorts, *viz.* one by a volley, and the other by a running fire, from the right to the left of the battalion or line.

REJOINER, in *Law*, the defendant's answer to the plaintiff's replication.

The order of the court of chancery is thus; first, the defendant puts in an answer or plea to the plaintiff's bill, which is sometimes also called an *exception*; the plaintiff's answer to this is called a *replication*; and the defendant's answer to that, a *rejoinder*.

The plaintiff may answer the rejoinder by a *sur-rejoinder*, upon which the defendant may *rebut*; and the plaintiff may answer him by a *sur-rebutter*; which pleas, replications, rejoinders, sur-rejoinders, rebutters, and sur-rebutters, answer to the *exceptio, duplicatio, triplicatio, and quadruplicatio* of the Roman laws. See PLEADING.

REJOINTING, or REJOYNTING, in *Architecture*, the filling up of joints of the stones in old buildings, &c. when worn hollow by the course of time, or by weather.

Rejointing is to be performed with the best mortar, as that of lime and cement; sometimes also with plaster; as in the joints of vaults, &c.

REIPOLTZHEIM, in *Geography*, a town of the duchy of Wurzburg; three miles N.E. of Schwarzbach.

REIPOLTZKIRCHEN, a castle of France, in the department of Mont Tonnerre, which gave name to a lordship, situated in the Hunfruck; five miles E. of Lautereck.

REIS, RE, or *Res*, in *Commerce*. See REES.

REISBACH, in *Geography*, a town of Lower Bavaria, in the Vils; 35 miles W. of Passau.

REISCH, a town of Moravia, in the circle of Iglau; 18 miles S. of Iglau.

REISCHSTADT, a town of Bohemia, in the circle of Boleslau; two miles N.W. of Nimes.

REIS-EFFENDI, in the *Turkish Empire*, one of the ten members of the *divan*, (which see,) or council of the grand visir, of which the visir and mufti are the presidents. The reis-effendi is a kind of secretary of state, high chancellor of the empire, and minister for foreign affairs. He signs all the orders of the Porte, which do not directly concern the finances and the military operations; he treats with all the European ministers who are at Constantinople: in a word, every thing that concerns the foreign powers, and

every thing that relates to the interior administration, pass through the channel of the reis-effendi; but he does nothing without communicating it to the grand visir, and taking his orders. In this council there are also two *ex-reis-effendi*.

REISENBERG, in *Geography*, a town of Aultria, on the Reifenspach river; 12 miles S.E. of Vienna.

REISENBURG, a town of Prussia, in the province of Oberland, built in the year 1169, and anciently the residence of the bishops of Pomerania. The chief subsistence of the inhabitants is derived from brewing and agriculture; near it is an ancient castle; 78 miles S.W. of Konigsberg.

REISENBERG, a town of Bohemia, in the circle of Koninggratz. N. lat. $50^{\circ} 40'$. E. long. $15^{\circ} 30'$.

REISENPACH, a river of Aultria, which runs into the Danube; 12 miles below Vienna.

REISHOFFEN, a town of France, in the department of the Lower Rhine; 21 miles N. of Strasburg.

REISJARVI, a town of Sweden, in the government of Ulea; 47 miles E. of Gamla Karleby.

REISKE, JOHN JAMES, in *Biography*, a learned philologist, born in 1716, at Zorlis, in Misnia, was the son of a tanner in that place. He was, at the age of twelve, sent to the orphan-school at Halle, where he made a rapid progress in the learning of the place. In 1733 he entered at the university of Leipzig, and being destined for the theological profession, he spent five years chiefly in the study of rabbinical writings, and in the study of the Arabic language. To the latter he became so ardently attached, and his passion for Arabic books was so strong, that he almost deprived himself of necessaries to purchase them. He went to Holland with the view of improving himself in his favourite language, and while there, he ransacked all the Oriental treasures of the library at Leyden, while, for his subsistence, he was obliged to become a corrector of the press. He passed his time in a state of indigence that brought upon him hypochondriac affections, the effects of which never left him. During his residence at Leyden, he was presented with a gratuitous degree in physic, but he never intended to avail himself of it in the way of practice: "Poverty," says his biographer, "was his perpetual companion, and his scanty resources were derived from correcting the press, translating, and performing other tasks for booksellers." Many learned pieces in Oriental and Greek literature occasionally proceeded from his pen, which made him well known in the learned world: and several of the works edited by him are held in very high estimation. He was at last nominated rector of the college of St. Nicholas, in Leipzig, a situation which enabled him to pursue his literary labours more according to his inclination. At the age of forty-eight he married Ernestine Muller, a young woman of twenty-five, who, under his instructions, acquired so much knowledge of the Greek and Latin, and some modern languages, that she became extremely useful to her husband in his editorial employments. He died at the age of fifty-eight, in the year 1774. Of the most valuable works of Reiske, are "Dissertatio de Principibus Muhamedanis qui aut ab Eruditione aut at Amore Literarum inclaruerunt;" "Animadversiones in Sophoclem;" "Animadversiones in Auctores Græcos;" "Oratorum Græcorum," 8 vols.; "Plutarchi Opera omnia;" "Maximi Tyrii Dissert.;" "Apparatus Critici ad Demosthenem," 3 vols. And after his death were published his "Conjecturæ in Jobum et Proverbia Salomonis, cum Oratione de Studio Arabice Linguae." The "Acta Eruditorum" were much indebted to the pen of Reiske.

REISNITZ, in *Geography*, a town of the duchy of Carinthia, four miles N.W. of Gottschee.

REISENDORF, a town of Silesia, in the principality of Neisse; four miles N. of Patshkau.

REISTEN, a town of the duchy of Wurzburg; six miles N.N.E. of Arnstein.

REISTERSTOWN, a post-town of America, in Baltimore county, Maryland; ten miles S.E. of Westminster.

REITERATED GRAFTING. See GRAFTING.

REITERATING, in *Printing*. See PRINTING.

REITERATION, the act of repeating a thing, or doing it a second time.

The church does not allow of the reiteration of baptism. St. Gregory observes, that it is no reiteration when there are wanting proofs of the thing's having been regularly done before.

REITLENGIN, in *Geography*. See REUTLENGIN.

REITTERECK, a town of Stiria; seven miles E. of Voitsburg.

REITTERS, an ancient title given the German cavalry. The word is originally High Dutch, and signifies a horseman, cavalier, or even knight.

REITZ, in *Geography*, a town of Portugal, in the province of Beira; three miles N. of Vifeu.

REKEK, a small island in the East Indian sea. S. lat. $1^{\circ} 33'$. E. long. $128^{\circ} 40'$.

RELAIS, in *Fortification*, a French term, the same with *berme*.

RELAND, ADRIAN, in *Biography*, an eminent orientalist and polite scholar, was born in the year 1676, at a village in North Holland. He was educated at Amsterdam, and made such progress in learning, that, having gone through the usual classical course when he was only eleven years old, he employed the next three years in making himself acquainted with the Hebrew, Syriac, Chaldee, and Arabic languages. At the age of fourteen he was sent to the university at Utrecht, and in three years was admitted to the degree of doctor in philosophy, and on this occasion he sustained a thesis "De Libertate Philosophandi." After a residence of six years at Utrecht he removed to Leyden, and was in a short time chosen by the earl of Portland as preceptor to his son. At the age of twenty-four, the university of Harderwyk nominated him to the chair of philosophy, but he did not remain long in that situation, for the university of Utrecht, on the recommendation of king William, invited him to the professorship of the Oriental languages and Jewish antiquities, which he accepted, and occupied with high reputation during the remainder of his life. He died at the age of 43, in the year 1719. Few writers have met with more general applause than Reland. His principal works, which are all extremely valuable, are; 1. "Palesina Monumentis veteribus illustrata," 2 vols. 4to. 2. "Dissertationes de nummis veterum Hebræorum." 3. "Antiquitates sacræ veterum Hebræorum." 4. "Introductio ad Grammaticam Hebræam." 5. "De Spoliis Templi Hierosolymitani in Arcu Titiano Romæ conspicuis." 6. "De Religione Muhamedica." Besides these he published many other things. In private life he was distinguished by his modesty, humanity, and learning, and carried on a correspondence with the most eminent scholars of his time. Moreri.

RELAPSE, in *Medicine*, the recurrence of a disease during the period of convalescence.

Relapses of all diseases, whether acute or chronic, are deemed more dangerous than the original attack; because the constitution, being already debilitated and reduced by the previous illness, is less capable of resisting the farther ravages of disease. This may be said to be true of all acute diseases,

diseases, such as fevers, dysenteries, inflammations of the lungs, liver, &c. Nevertheless, relapses of these disorders are not always fatal; because, as the weaker constitution is less capable of being excited to violent action, so these second attacks are sometimes milder, and more easily influenced by remedies. Relapses of chronic diseases, such as dropsies or jaundice, are more unfavourable; because their recurrence implies that the internal disease, from which they originate, is not removed, but has only been temporarily alleviated.

RELATIO, Lat., *Relation*, Eng., in *Musick*. Relative sounds are in general such as belong to two or more chords, as in the key of C. The chords of A, F, G, and E, are relative chords; as E, the 5th of A, is 3d of C: in the chord of F, C is the 5th; in the chords of G and E, each of those sounds is a part of the chord of C.

The relatives to A minor are obvious here.

In the modulation by rising and falling a 3d in the base, two relative notes are in common with each chord. The most agreeable relation of a minor key to a major, is in the modulation from a minor key to the 3d above: as from A to C, or D to F; the scales of both keys being the same in descending. But falling a 3d in the base from a minor 3d to a major, as from A to F, or from D to Bb, is still more pleasing.

False relation is C* against C#, or G* in the chord of C#. But even these false relations are allowed now, as *passing-notes* of taste, though not in the body of the harmony.

RELATION, RELATIO, in *Philosophy*, the mutual respect of two things; or what each is with regard to the other.

The word is formed *a referendo*: relation consisting in this, that one thing is referred to another: whence it is also called *respect*, *habitude*, and *comparison*.

The idea of relation we acquire, when the mind so considers any thing, that it doth, as it were, bring it to, and set it by, another, and carry its view from the one to the other. Hence the denominations given to things intimating this respect, are called *relatives*; and the things so brought together, are said to be *related*.

Thus, when I call Caius *husband*, or this wall *whiter*, I intimate some other person or thing in both cases, with which I compare *him* or *it*. Hence the wall is called by the schoolmen the *subject*; the thing it exceeds in whiteness, the *term*; and the whiteness, the *foundation* of the relation.

Relation may be considered two ways; either on the part of the mind referring one thing to another; in which sense relation is only a mode or affection of the mind, by which we make such comparison; or on the part of the things referred, which being no other than ideas, relation, in this sense, is only a new idea resulting or arising in the mind upon considering of two other ideas. So that relation, take it as you will, is only in the mind, and has nothing to do with the things themselves.

Any of our ideas, Mr. Locke observes, may be the foundation of relation. Though where languages have failed to give correlative names, the relation is not easily taken notice of; as in concubine, which is a relative name, as well as wife.

There is, in effect, no idea but is capable of an infinite number of relations: thus, one single man may at once sustain the relations of father, brother, son, husband, friend, subject, general, European, Englishman, islander, master, servant, bigger, less, &c. to an almost infinite number; he being capable of as many relations as there can be occasions of comparing him to other things in any manner of agreement or disagreement, or any respect whatsoever.

The ideas of relations are much clearer and more distinct than those of the things related; because the knowledge of one simple idea is oftentimes sufficient to give the notion of a relation; but, to the knowing of any substantial being, an accurate connection of several ideas is necessary.

The perception we have of the relations between the various ideas in which the mind acquiesces, makes what we call *judgment*. Thus, when I judge that twice 2 make 4, or do not make 5, I only perceive the equality between twice 2 and 4, and the inequality between twice 2 and 5.

The perception we have of the relations between the relations of various things, constitutes what we call *reasoning*. Thus, when from this that 4 is a smaller number than 6, and that twice 2 is equal to 4, I gather, that twice 2 is a less number than 6; I only perceive together the relation of the numbers twice 2 and 4, and the relation of 4 and 6.

The ideas of cause and effect, we get from our observation of the vicissitude of things, while we perceive some qualities or substances begin to exist, and that they receive their existence from the due application and operation of other beings. That which produceth, is the cause; that which is produced, is the effect.

Thus, fluidity in wax is the effect of a certain degree of heat, which we observe to be constantly produced by the application of such heat.

The denominations of things taken from time are, for the most part, only relations. Thus, when it is said, that queen Elizabeth lived sixty-nine, and reigned forty-five years, no more is meant, than that the duration of her existence is equal to sixty-nine, and of her government to forty-five, annual revolutions of the sun; and so are all words answering to how long.

Young and old, and other words of time, that are thought to stand for positive ideas, are indeed relative, and intimate a relation to a certain length of duration, of which we have the ideas in our minds. Thus, we call a man young or old, that had lived little or much of that time which men usually attain to: and thus a man is called young at twenty, but a horse old at the same period.

There are other ideas that are truly relative, which we signify by names that are thought positive and absolute; such as great and little, strong and weak. The things thus denominated

minated are referred to some standards, with which we compare them: thus, we call an apple *great*, which is bigger than the ordinary sort of those we have been used to; and a man *weak*, that has not so much strength or power to move as men usually have, or as others of his own size have.

Authors give various divisions of relations. The school philosophers commonly divide them into those of *origination*, under which are comprehended the relations of cause and effect; those of *negation*, which are between opposite things; and those of *affirmation*, which are relations of agreement between whole and part, the sign and thing signified, the adjunct and subject. This division is founded upon this, that the mind can only compare things three ways; *viz.* by inferring, denying, and affirming.

Others divide relations into those of *origination*; those of *agreement*, *e. gr.* similitude, parity, &c.; those of *diversity*; and those of *orders*, as priority, posteriority, &c.

Others divide them into *predicamental* and *transcendental*. Under the first come those relations between things that belong to the same predicament, *e. gr.* between father and son. To the latter belong those which are more general than the predicaments, or are of different predicaments; as the relations of substance and accident; of cause and effect; and of Creator and creature.

Mr. Locke gives us a distribution of relations on a different principle. All simple ideas, he observes, in which are parts or degrees, afford an occasion of comparing the subjects in which they are to one another, in respect of those simple ideas; as whiter, sweeter, more, less, &c. These, depending on the equality and excess of the same simple idea, in several subjects, may be called *proportional* relations.

Another occasion of comparing things being taken from the circumstances of their origin, as father, son, brother, &c. these may be called *natural* relations.

Sometimes the foundation of considering things is some act, by which any one comes by a moral right, power, or obligation, to do something: such are general, captain, burgher: these are *instituted* and *voluntary* relations, and may be distinguished from the natural, in that they are alterable and separable from the persons to whom they sometimes belonged, though neither of the substances so related be destroyed. But natural relations are not alterable, but are as lasting as their subjects.

Another relation is the conformity or disagreement of men's voluntary actions to a rule, to which they are referred, and by which they are judged of: these may be called *moral* relations.

It is this conformity or disagreement of our actions to some law (by which good or evil is drawn on us from the will and power of the law-maker, and is what we call *reward* or *punishment*) that renders our actions morally good or evil.

Of these moral rules or laws there seem to be three sorts, with their different enforcements. First, the divine law; secondly, civil law; thirdly, the law of opinion or reputation. By their relation to the first, our actions are either sins or duties; to the second, criminal or innocent; to the third, virtues or vices. Locke's Essay, vol. i. chap. 25, 26, 33.

RELATION, in *Logic*, is an accident of substance, accounted one of the ten categories or predicaments.

Each substance admits of an infinity of relations. Thus the same Peter considered with regard to Henry, is in the relation of a master; with regard to John, in that of a tenant; with regard to Mary, in that of a husband, &c.

Again, with regard to one person, he is rich; with regard to another, poor; with regard to another, he is far, near, tall, short, a neighbour, stranger, learned, unlearned, good, bad, equal, &c. It is disputed among the school philosophers, whether or no the relation be a thing formally and really distinct from the foundation of the substance.

RELATION, *Relatio*, in *Rhetoric*, is sometimes used to signify the same with *recrimination*; which see.

RELATION is also used, in the *School Theology*, to denote certain of the divine perfections, called *personal* ones; because by these one Divine Person is referred to another, and distinguished from it.

Hence the schoolmen teach, that in God there is one nature, two processions, three persons, and four relations.

These relations are paternity, filiation, active spiration, and passive spiration.

RELATION, in *Geometry*, *Arithmetic*, &c. is the habitude, or respect of two quantities to one another, with regard to their magnitude. This we more usually call *ratio* or *reason*. See RATIO.

The equality or sameness of two such relations we call *proportion*; which see.

RELATION, in *Grammar*, is the correspondence which words have to one another in *construction*; which see. See also REGIMEN and SYNTAX.

Faulty and irregular relations are the things chiefly to be guarded against in writing correctly; they make the sense obscure, and frequently equivocal. Thus: the orator was attended to with a coldness, which was the more remarkable, as the audience were under some emotion before he began. Here coldness being put indeterminately, the relative *which* can have no just and regular relation to it.

RELATION is also frequently used for analogy, or what several things have in common. See ANALOGY.

In painting, architecture, &c. a certain relation of the several parts and members of the building, or picture, constitutes what we call *symmetry*; which see.

RELATION, in *Law*, is where two things, as times, &c. are considered as if they were one; the thing subsequent being considered as taking effect, by relation, at the time preceding.

As if A deliver a writing to B, to be delivered to C, as the deed of A; the writing shall be deemed to be delivered to C, at the time when it was given to B, by relation.

When the execution of a thing is done, it hath relation to the thing executory, and makes all but one act to record, although performed at several times. (1 Rep. 199.) Judgment shall have relation to the first day of the term, as if given on that very day, unless there is a memorandum to the contrary; as where there is a continuance till another day in the same term. (3 Salk. 212.) A verdict was given in a cause for a plaintiff, and there was a motion in arrest of judgment within four days; the court took time to advise, and in four days afterwards the plaintiff died: it was adjudged, that the favour of the court shall not prejudice the party, for the judgment ought to have been given after the first four days; and though it is given after the death of the party, it shall have relation to the time when it ought to have been given. (1 Leon. 187.) Rule was had for judgment, and two days after the plaintiff died; yet the judgment was entered, because it shall have relation to the day when the rule was given, which was when the plaintiff was alive. (Poph. 132.) Judgment against an heir of the obligation of his ancestor shall have relation to the time of the writ *fi. rel.* purchased; and from that time it will

will avoid all alienation made by the heir. (Cro. Car. 102.) If one be bail for a defendant, and before judgment he leaves his lands; they shall be liable to the bail, and judgment by relation.

By stat. 29 Car. II. c. 3. § 16. writs of execution shall bind the property of goods taken in execution, only from the time of their delivery to the officer. Sale of goods of a bankrupt, by commissioners, shall have relation to the first act of bankruptcy; and be good, notwithstanding the bankrupt sells them afterwards. (Stat. Jac. I. c. 15.) If a man buys cattle in a market, which are stolen, and selleth them out of the market, though the cattle are afterwards brought into the market, and the second bargain confirmed, and money paid, &c., this bargain will not be good; for it shall have relation to the beginning, which was unlawful. (Dyer 99.) Fines, being but common assurances, shall be guided by the indentures precedent; and the execution of them have relation to the original act. (Cro. Jac. 110.) Letters of administration relate to the death of the intestate, and not to the time when they were granted.

So bills in parliament to which the king assents on the last day of parliament, shall relate and be of force from the first day thereof. Coke calls this *fidio juris*.

RELATION, in *Music*. See RELATIO.

RELATIVE PROPOSITIONS, are such as include some relation and comparison.

Thus, where the treasure is, there will the heart be; As much as thou hast, so much thou art worth, &c. are relative propositions.

RELATIVE *gravity, levity, motion, necessity, place, space, time, velocity*. See the several substantives.

RELATIVE *Terms*, in *Logic*, are words which imply a relation, or a thing considered as compared to another.

Relative terms include a kind of opposition between them; yet so, as that the one cannot be without the other.

Such are *father and son, husband and wife, king and subjects, &c.*

RELATIVE, in *Grammar*, is a word or term, which in the construction answers to some word foregoing, called the *antecedent*; which see.

All relatives are said to reciprocate, or mutually infer each other; and, therefore, they are often expressed by the genitive case.

RELATIVE *Pronoun*. See PRONOUN.

RELATOR, in *Law*, a rehearer, or teller, applied to an informer. See INFORMATION.

RELAXATION, in *Law*, is used for a *releasing*. See RELEASE.

In this sense, we say the relaxation of an attachment in the court of admiralty.

The tenor of indulgence is a relaxation, or a diminution, of the pains of purgatory.

RELAXATION, in *Surgery*, is a preternatural extension, or straining of a nerve, tendon, muscle, or the like; either through violence or weakness.

Hernias are descents or relaxations of the intestines, &c.

From the same cause arise descents or prolapsions of the anus, &c.

RELAY, a fresh equipage, horse, &c. sent before, or appointed to be ready, for a traveller to change, to make the greater expedition; as in riding post.

The term is borrowed from the French, *relais*, which signifies the same thing. In France, the general of the posts entitles himself superintendent of the relays.

RELAY *Horses*, in the *Artillery*, are horses that march

with the artillery or baggage, and are ready to relieve others, or to assist in going up a hill, or through bad roads, &c.

RELAYS, in *Hunting*, are fresh sets of dogs, or horses, or both, disposed here and there for readiness, in case the game come that way, to be cast off, or to mount the hunters in lieu of the former, which are supposed to want respite.

RELAY, in *Tapestry*, is an opening left in a piece of tapetstry, where the colours or figures are to be changed; because on those occasions, the workmen are changed; or else the places are left to be filled up, till the rest of the work is done. See TAPESTRY.

RELEASE, RELAXATIO, in *Law*, denotes an instrument, by which estates, rights, titles, entries, actions, and other things, are sometimes extinguished and annulled, sometimes transferred, sometimes abridged, and even sometimes enlarged: and it is a species of conveyance which presupposes some other conveyance precedent, and serves to enlarge, confirm, alter, restrain, restore, or transfer the interest granted by such original conveyance.

A release is either in fact or in law. A release *in fact*, is that which the very words do expressly declare.

A release *in law*, is that which acquits by way of consequence, or intendment of law. A release is the giving or discharging of a right of action, which a man hath claimed, or may claim, against another, or that which is his: or it is the conveyance of a man's interest or right which he hath to a thing, to another who hath possession of it, or some estate in it. (4 New Abr.) According to Coke releases are distinguished into express releases in deed, and those arising by operation of law; and are made of lands and tenements, goods and chattels; or of actions real, personal and mixed. (1 Inst. 264.) Releases of land may enure, or take effect, either, 1. By way of *enlarging an estate, or enlarger l'estate*: as if there be tenant for life or years, remainder to another in fee, and he in remainder releases all his right to the particular tenant and his heirs, this gives him the estate in fee. (Litt. § 465.) But in this case the releasor must be in possession of some estate, for the release to work upon: for if there be a lessee for years, and, before he enters and is in possession, the lessor releases to him all his rights in the reversion, such release is void for want of possession in the releasor. (Litt. § 459.) But when it is said, that a release, which enures by enlargement, cannot work without a possession, it must be understood to mean, not that an actual estate in possession is necessary, but that a "vested interest" suffices for such a release to operate upon. By comparing this with the operation of a LEASE and Release (which see) it will be seen, that not only estates in possession, but estates in remainder and reversion, and all other incorporeal hereditaments, may be effectually granted and conveyed by lease and release; but it is an inaccuracy to say, that the releasors are, in these cases, in actual possession of the hereditaments: the right expression is, that they are actually vested in him, by virtue of the lease in possession and the statute. 1 Inst. 270. (a) n. 3.

To make releases operate by enlargement, it is generally necessary, that the releasor, at the time the release is made, should be in actual possession of, or have a vested interest in, the lands intended to be released; that there should be a privity between him and the releasor; and that the possession of the releasor should be notorious.

2. By way of *passing an estate, or mitter l'estate*: as when one or two co-parceners releaseth all her right to the other, this passeth the fee-simple of the whole.

(1 Inst.

(1 Inst. 273.) And in both these cases there must be a privity of estate between the releasor and the releasee; that is, one of their estates must be so related to the other, as to make but one and the same estate in law.

3. By way of *passing a right*, or *mitter le droit*: as if a man be disseised, and releaseth to his disseisor all his right; hereby the disseisor acquires a new right, which changes the quality of his estates, and renders that lawful which before was tortious or wrongful. (Litt. §. 466.)

4. By way of *extinguishment*: as if my tenant for life makes a lease to A for life, remainder to B and his heirs, and I release to A; this extinguishes my right to the reversion, and shall enure to the advantage of B's remainder as well as of A's particular estate. (Litt. §. 470.)

5. By way of *entry and seignment*: as if there be two joint disseisors, and the disseisee releases to one of them, he shall be sole seised; and shall keep out his former companion; which is the same in effect as if the disseisee had entered, and by that means put an end to the disseisin, and afterwards had enfeoffed one of the disseisors in fee. (1 Inst. 278.) And hereupon we may observe, that when a man has in himself the possession of lands, he must at the common law convey the freehold by feoffment and livery; which makes a notoriety in the country: but if a man has only a right or a future interest, he may convey that right or interest by a mere release to him that is in possession of the land: for the occupancy of the releasee is a matter of sufficient notoriety already. Blackst. Com. book ii. See *LEASE and Release*.

Littleton says, that the proper words of a release are "remissio, relaxatio, and quietum clamatio," which have all the same signification. Lord Coke adds, "renunciare, acquietare," and says, that there are other words which will amount to a release; as, if the lessor grants to the lessee for life, that he shall be discharged of the rent; this is a good release. (Litt. § 445. 1 Inst. 264. Plowd. 140.) So a pardon, by act of parliament, of all debts and judgments, amounts to a release of the debt: the word pardon including a release. (1 Sid. 261.) An express release must regularly be in writing and by deed, according to the common rule, "eodem modo oritur, eodem modo dissolvitur," so that a duty arising by record must be discharged by matter of as high a nature: so of a bond or other deed. (Co. Litt. 264. b. 1 Rol. Rep. 43. 2 Leon. 76. 213. 2 Rol. Abr. 408. 2 Sand. 49. Morr. 573. pl. 787.) But a promise by words may, before breach, be discharged or released, by word of mouth only. (1 Sid. 177. 2 Sid. 78. Cro. Jac. 483. 620. See Cro. Car. 383. 1 Mod. 262. 2 Mod. 259. 1 Sid. 293.) A release of a right in chattels cannot be without deed. (1 Leon. 283.) A covenant perpetual, as that the covenantor will not sue beyond a certain limitation of time, is an absolute release. But if the covenant be, that he will not sue *till* such a time, this does not amount to a release, nor is pleadable in bar as such, but the party hath remedy only on his covenant. If two are jointly and severally bound in an obligation, and the obligee, by deed, covenants and agrees not to sue one of them; this is no release, and he may notwithstanding sue the other. (Cro. Car. 551. 2 Salk. 575.) But if two are jointly and severally bound, a release to one discharges the other. L. Raym. 420.

It seems agreed, that a will, though sealed and delivered, cannot amount to a release; and, therefore, where in debt on an obligation, by the representative of a testator, a defendant pleaded, that the testator by his last will in writing released to the defendant; this was adjudged ill; and that no advantage could be taken by plea. (1 Sid. 421.) But it hath been held in equity, that though a will cannot enure

as a release, yet provided it were expressed to be the intention of the testator that the debt should be discharged, the will would operate accordingly; and that, in such case, it would be plainly an absolute discharge of the debt, though the testator had survived the legatee. (1 P. Wms. 85. 2 Vern. 521.) If a debt is mentioned to be devised to the debtor, without words of release, or discharge of the debt, and the debtor die before the testator, this will not operate as a release, but will be considered as a lapsed legacy, and the debt will subsist. (2 Vern. 522.) A debt is only a right to recover the amount of the debt by way of action; and as an executor cannot maintain an action against himself, or against a co-executor, the testator, by appointing the debtor an executor of his will, discharges the action, and consequently discharges the debt. Still, however, when the creditor makes the debtor his executor, it is to be considered merely as a specific bequest or legacy, devised to the debtor to pay the debt; and, therefore, like other legacies, it is not to be paid or retained till the debts are satisfied; and if there be not assets for the payment of the debts, the executor is answerable for it to the creditors. In this case, it is the same whether the executor accepts or refuses the executorship. On the other hand, if the debtor makes the creditor his executor, and the creditor accepts the executorship, if there be assets, he may retain his debt out of the assets against the creditors in equal degree with himself; but if there be not assets, he may sue the heir, when the heir is bound. 1 Inst. 264. b in n. See *EXECUTOR*.

Littleton says, that a release of all demands is the best release to him, to whom it is made; and Coke says, that the word "demand" is the largest word in law, except "claim;" and that a release of all demands discharges all sorts of actions, rights, and titles, conditions before or after, breach, executions, appeals, rents of all kinds, covenants, annuities, contracts, recognizances, statutes, commons, &c. (Litt. § 508. Co. Litt. 291.) A release of all actions discharges a bond to pay money on a future day. But a release of actions does not discharge a rent before the day of payment. (Co. Litt. 292.) By a release of all manner of actions, all actions, as well criminal as real, personal and mixed, are released. Co. Litt. 287. See *Jacob's Law Dict.* by Tomlins.

RELEGATION, RELEGATIO, a kind of exile or banishment, by which the obnoxious person is commanded to retire to a certain place prescribed, and to continue there till he be recalled.

Lord Coke calls relegation a banishment for a time only; Courtin more adequately defines relegation a banishment to a certain place for a certain term.

In Rome, relegation was a less severe punishment than deportation, in that the relegated person did not thereby lose the rights of a Roman citizen, nor those of his family, as the authority of a father over his children, &c.

RELHANIA, in *Botany*, received that name from the pen of the late M. l'Heritier, in honour of the Rev. Richard Relhan, F.R.S. and A.L.S., author of the *Flora Cantabrigiensis*. — L'Herit. Sert. Angl. 22. Schreb. 563. Willd. Sp. Pl. v. 3. 2135. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 91. Thunb. Prodr. 145. Poir. in Lamarck Dict. v. 4. 93. (Eclupes; Gært. t. 169. Lamarck Illustr. t. 689.)—Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common calyx* oblong, imbricated, with oblong chaffy scales. *Cor.* compound, radiated; united florets in the disk numerous, tubular, funnel-shaped, five-lobed; female ones in the radius ligulate, ovate-oblong.

Stam.

Stam., in the perfect florets, filaments five, very short; anthers combined into a tube. *Pist.* in the perfect florets, germen oblong; style simple; stigmas two, reflexed: in the female ones, germen oblong, rather incurved; style simple; stigmas two, recurved. *Peric.* none, except the permanent unchanged calyx. *Seeds*, to all the florets alike, solitary, angular, with a membranous, many-cleft, short crown. *Recept.* chaffy.

Ess. Ch. Receptacle chaffy. Seed-crown membranous, short, cylindrical. Calyx imbricated, chaffy. Florets of the radius numerous.

M. l'Heritier distinguishes this genus from *Athanasia* by the presence of a radius; from *Osmites* by the florets of that radius producing perfect seeds; and from *Leysera* by the want of a feathery seed-down. Gärtner remarks that his *Eclopes*, adopted from Sir Joseph Banks's and Dr. Solander's papers, is nothing more than an *Athanasia*, furnished with a radius. A due attention to the syngeneisous class soon teaches us to mistrust this character, which is unstable, even in several species of that class; witness the genera *Coreopsis* and *Bidens*. Still less is the fertility or barrenness of the radiant florets capable of distinguishing natural genera, though Linnæus has, unadvisedly, founded a distinction of orders, in the class in question, upon those differences. We cannot but assent, therefore, to the opinion of Poiret, that the genus of *Relhania* is not naturally distinct from the Linnæan *Osmites*, at least, which last name being already established, ought to have been retained. However striking the radiating, chaffy, shining inner scales of the calyx may be in a few species of *Osmites*; approaches towards that character are found in the *Relhania*, as *genistifolia*, and still more in *paleacea*. We are far from intending to do away the claims of our friend, Mr. Relhan, to botanical commemoration, even were that honour bestowed in general far less indiscriminately than it is. For the present, the *Relhania* of L'Heritier is received; and if that be at any time abolished, there ought to be one established on more solid principles.

Willdenow has nineteen species of this supposed genus; all natives of the Cape of Good Hope, mostly of a shrubby bushy habit, green-house plants in England, where only one of them indeed appears to be cultivated. Their flowers are mostly corymbose, small, of a dull yellow, not remarkable for beauty. We select a few examples.

R. squarrosa. Hook-leaved Relhania. Willd. n. 1. Ait. n. 1. (*Athanasia squarrosa*; Linn. Sp. Pl. 1180. Amœn. Acad. v. 6. 98. *Santolina squarrosa*; Linn. Am. Acad. v. 4. 329.)—Leaves elliptical, pointed; recurved at the point.—Sent to Kew by Mr. Masson, in 1794. It flowers in the green-house in May and June. The whole *strub* is smooth, much branched. *Leaves* numerous, somewhat imbricated, about a quarter of an inch long, elliptical, obscurely single-ribbed beneath, entire, acute; strongly recurved, smooth, finely dotted on both sides. *Flowers* solitary, on slender axillary stalks, thrice the length of the leaves. *Calyx* about half an inch long, very smooth, rather shining. This should seem a different plant from *R. squarrosa* of Thunberg, who defines his "with terminal umbels," and has thus led Willdenow, contrary to the description of Linnæus, to refer the species in question to the first section of the genus, "with aggregate flowers." It appears, by specimens in the Linnæan herbarium, that the *flowers* are sometimes so crowded about the ends of the branches, as to assume a corymbose appearance, though each stalk is really axillary. Such a specimen probably was described by Thunberg.

R. genistifolia. Broom-leaved Relhania. Willd. n. 2.

(*Athanasia genistifolia*; Linn. Syst. Nat. ed. 12. v. 2. 540. Mant. 464.)—Leaves obovato-lanceolate, pointed, single-ribbed beneath, entire, smooth, somewhat imbricated. Flowers terminal, umbellate.—A bushy *strub*, very much branched. *Leaves* a quarter of an inch, or hardly so much, in length, numerous, crowded, dotted, entire, smooth; the lower ones obovate, and smallest; the upper more lanceolate and elongated; all bluntish, with a minute, often hooked, point, and single-ribbed at the back only. *Flowers* smaller than the preceding, from five to eight together, in little terminal umbels. *Calyx* shining.

R. viscosa. Glutinous Relhania. L'Herit. Sert. 23. Willd. n. 5. (*Eclopes viscosa*; Gärtn. v. 2. 440. t. 169.)—Leaves linear-lanceolate, pointed, viscid, obscurely single-ribbed beneath, rather fleshy; the upper ones somewhat crenate.—The *flowers* are much like the last-mentioned; but the *leaves* are twice as large, more elongated in shape, more slightly ribbed, the edges of the upper ones rough or crenate, and all of them extremely glutinous. When bruised, the dried *leaves* are found to retain a powerful aromatic scent, approaching to that of orange-peel.

R. pedunculata. Long-stalked Dwarf Relhania. L'Herit. Sert. Angl. 23. Willd. n. 7. (*R. pumila*; Thunb. Prodr. 146. *Athanasia pumila*; Linn. Suppl. 362. *Zoega capensis*; *ibid.* 382.)—Leaves linear, villous, and glandular. Stem diffuse. Flower-stalks axillary, much longer than the leaves.—A small herbaceous annual species, whose *root* is furnished with numerous capillary fibres. *Stem* a span high, branched from the base, round, purplish, spreading; glandular and slightly cottony in the upper part, as well as the *leaves*; which are about an inch long, very narrow, somewhat triangular. *Flowers* small, yellow, on long, stoutish, downy, axillary stalks, about the summits of the branches. This occurs twice in the *Supplementum*, having, in one instance, been described by Linnæus himself, from a wild specimen, and in the other, adopted by his son, unfeen, from Thunberg's communications.

R. paleacea. Chaffy-flowered Relhania. L'Herit. Sert. Angl. 24. Willd. n. 11. Thunb. Prodr. 146. (*Leysera paleacea*; Linn. Syst. Veg. ed. 13. 641. *L. ericoides*; Berg. Cap. 294. *Eclopes*; Lamarck f. 2? *Asterophorus fruticosus luteus, foliis rosifmarini crebris, ovarii hirsutis*; Vaill. Aët. German edition, 585.)—Leaves linear, triangular, channelled, hoary; recurved at the point. *Flowers* terminal, solitary, sessile. *Calyx* turbinate.—Communicated by Van Royen to Linnæus, and by Sherard, as it appears, to Vaillant. The *stem* is shrubby, a span high, branched. *Leaves* numerous, about an inch long, narrow, clothed, as well as the young *branches*, with fine hoary down. *Calyx* ovate, smooth, a quarter of an inch in diameter; its inner scales much elongated, lanceolate, acute, and membranous, resembling the scales of the *receptacle*, which stand prominent and erect, above the florets of the disk. This plant has so much of the external aspect of *Leysera gnaphalodes*, that we can hardly wonder at Linnæus, for having referred it, by the habit alone, to the same genus. Upon a careful examination, however, the characters, and even the appearance, of the parts of fructification, are abundantly different in the two plants.

Most of the other species of *Relhania*, in Willdenow, are adopted from the short specific definitions of Thunberg and L'Heritier; nor have we been able to determine them all with certainty. It is remarkable that no figure of any has appeared, except in Gärtner and Lamarck, nor is the latter very happy or discriminative, in what he has exhibited of this genus, called by him, after Gärtner, *Eclopes*.

RELICS, RELIQUÆ, in the *Ramiff Church*, certain remains

remains of the body or clothes of some faint or martyr, devoutly preserved in honour to his memory, carried at processions, killed, revered, &c.

The abuses of that church in point of relics have been very flagrant. F. Mabillon, a Benedictine, complains of the great number of suspected relics exposed on altars: he owns, that were there to be a strict inquisition into the relics, vast numbers of spurious ones would be found offered every where to the piety and devotion of the faithful; and adds, that bones are frequently consecrated, so far from belonging to faints, that, in all probability, they do not belong to Christians.

The catacombs are an inexhaustible fund of relics; yet it is still disputed who were the persons interred in them.

In the eleventh century, a method was introduced of trying supposed relics by fire. Those which did not consume in the fire were reputed genuine; the rest not.

It is an ancient custom, which still obtains, to preserve the relics in the altars on which mass is celebrated. To this purpose, a square hole is made in the middle of the altar, big enough to receive the hand; and in that is the relic deposited, being first wrapped in red silk, and inclosed in a leaden box.

The Romanists allege a considerable degree of antiquity in behalf of their relics. The Manichees, it seems, out of hatred to the flesh, which they held an evil principle, are recorded as refusing to honour the relics of faints; which is esteemed a kind of proof, that the Catholics did it in the first ages.

Indeed, folly and superstition blended themselves with religion at too early a period. Even the touching of linen cloths on relics, from an opinion of some extraordinary virtue derived from them, appears to be as ancient as the first ages; there being a hole made in the coffins of the forty martyrs at Constantinople, expressly for this purpose.

This practice of honouring the relics of faints, on which the church of Rome, in succeeding ages, founded her superstitious and lucrative use of them, as objects of devotion, as a kind of charms or amulets, and as instruments of pretended miracles, seems to have originated in a very ancient custom, that prevailed among Christians, of assembling at the cœmeteries or burying-places of the martyrs, for the purpose of commemorating them, and of performing divine worship. When the profession of Christianity obtained the protection of the civil government, under Constantine the Great, stately churches were erected over their sepulchres, and their names and memories were treated with every possible token of affection and respect. (See SAINTS.) In process of time, this reverence of the martyrs exceeded all reasonable bounds; and those prayers and religious services were thought to have a peculiar sanctity and virtue, which were performed over their tombs. Hence probably proceeded the practice, already mentioned, which obtained in the fourth century, of depositing relics of the faints and martyrs under the altars in all their churches. This practice, however, was then thought of such importance, that St. Ambrose would not consecrate a church, because it had no relics; and the council of Constantinople in Trullo ordained, that those altars should be demolished, under which there were found no relics. The rage of procuring relics for this and other purposes of a similar nature became so excessive, that, in 386, the emperor Theodosius the Great was obliged to pass a law, forbidding the people to dig up the bodies of the martyrs, and to traffick in their relics.

Such was the commencement of that respect for sacred

relics, which, in after ages, was perverted into a formal worship of them, and became the occasion of innumerable processions, pilgrimages, and miracles, from which the church of Rome hath derived incredible advantage. Towards the close of the ninth century, it was not enough to reverence departed faints, and to confide in their intercessions and succours: it was not enough to clothe them with an imaginary power of healing diseases, working miracles, and delivering from all sorts of calamities and dangers; their bones, their clothes, the apparel and furniture they had possessed during their lives, the very ground which they had touched, or in which their putrified carcases were laid, were treated with a stupid veneration, and supposed to retain the marvellous virtue of healing all disorders both of body and mind, and of defending such as possessed them against all the assaults and devices of Satan. The consequence of this wretched notion was, that every one was eager to provide himself with these salutary remedies; for which purpose, great numbers undertook fatiguing and perilous voyages, and subjected themselves to all sorts of hardships; while others made use of this delusion, to accumulate their riches, and to impose upon the miserable multitude by the most impious and shocking inventions. As the demand for relics was prodigious and universal, the clergy employed all their dexterity to satisfy these demands, and were far from being nice in the methods they used for that end. The bodies of the faints were sought by fasting and prayer, instituted by the priest, in order to obtain a divine answer and an infallible direction; and this pretended direction never failed to accomplish their desires: the holy carcase was always found, and that always in consequence, as they impiously gave out, of the suggestion and inspiration of God himself. Each discovery of this kind was attended with excessive demonstrations of joy, and animated the zeal of these devout seekers to enrich the church still more and more with this new kind of treasure. Many travelled with this view into the Eastern provinces, and frequented the places which Christ and his disciples had honoured with their presence, that, with the bones and other sacred remains of the first heralds of the gospel, they might comfort dejected minds, calm trembling consciences, save sinking states, and defend their inhabitants from all sorts of calamities. Nor did these pious travellers return home empty; the craft, dexterity, and knavery of the Greeks found a rich prey in the stupid credulity of the Latin relic-hunters, and made a profitable commerce of this new devotion. The latter paid considerable sums for legs and arms, skulls and jaw-bones, (several of which were Pagan, and some not human,) and other things that were supposed to have belonged to the primitive worthies of the Christian church: and thus the Latin churches came to the possession of those celebrated relics of St. Mark, St. James, St. Bartholomew, Cyprian, Pantaleon, and others, which they shew at this day with so much ostentation. But there were many, who, unable to procure for themselves these spiritual treasures by voyages and prayers, had recourse to violence and theft: for all sorts of means, and all sorts of attempts, in a cause of this nature were considered, when successful, as pious and acceptable to the Supreme Being.

Besides the arguments from antiquity to which the Papists refer, in vindication of their worship of relics, of which the reader may form some judgment from this article, Bellarmine appeals to scripture in support of it, and cites the following passages, *viz.* Exod. xiii. 19. Deut. xxxiv. 6. 2 Kings, xiii. 21. 2 Kings, xxiii. 16, 17, 18. Isaiah, xi. 10. Matth. xi. 20, 21, 22. Acts, v. 12—15. Acts, xix. 11, 12. See POKERY.

Relics are forbidden to be used or brought into England by several statutes; and justices of peace are empowered to search houses for Popish books and relics, which, when found, are to be defaced and burnt, &c. 3 Jac. I. cap. 26.

RELICT, RELICTA, in *Law*. See WIDOW.

RELICTA VERIFICATIONE, is when a defendant relinquishes his proof or plea, and thereupon judgment is entered for the plaintiff.

RELIEF, RELEVUM, *Levamen*, a fine paid the chief lord, by a person at his coming to the inheritance of land held by military service.

This was said *relevare hereditatem caducam*; and the money thus paid was called *relevamen*, *relevum*, or *relief*. Relief is usually to the value of a year's rent or revenue.

The origin of the custom is thus: a feudatory or beneficiary estate in lands being at first only granted for life, after the death of the vassal, it returned to the chief lord; and was hence called *feudum caducum*, *q. d.* fallen to the lord by the death of the tenant.

In course of time, these feudatory estates being converted into inheritances by the connivance and consent of the lord; when the possessor of such estate died, it was called *hereditas caduca*, *q. d.* an inheritance fallen to the lord, from whom it was to be recovered, by the heir's paying a certain sum of money. But this sum was arbitrary, and at the will of the lord; so that, if he pleased to demand an exorbitant relief, it was in effect to disinherit the heir. The English ill brooked this consequence of their new-adopted policy; and, therefore, William the Conqueror by his laws (cap. 22, 23, 24.) ascertained the relief, by directing (in imitation of the Danish heriots), that a certain quantity of arms and habiliments of war should be paid by the earls, barons, and vavassours respectively; and if the latter had no arms, they should pay 100*s.* William Rufus broke through this composition, and again demanded arbitrary uncertain reliefs, as due by the feudal laws; thereby in effect obliging every heir to new-purchase or redeem his land: but his brother Henry I. by his charter, restored his father's law; and ordained that the relief to be paid should be according to the law so established, and not an arbitrary redemption. But afterwards, when, by an ordinance in 27 Hen. III. called the Assise of Arms, it was provided that every man's armour should descend to his heir, for defence of the realm, and it thereby became impracticable to pay these acknowledgments in arms, according to the laws of the Conqueror, the composition was universally accepted of 100*s.* for every knight's fee; as we find it ever after established. (Glanv. l. ix. c. 4. Litt. § 112.) But it must be remembered, that this relief was only then payable, if the heir at the death of his ancestor had attained his full age of twenty-one years.

RELIEF, *Reasonable*, called also *lawful* and *ancient* relief, is that enjoined by some law, or fixed by ancient custom; and which does not depend on the will of the lord.

Thus in a charter of king John, mentioned by Matthew Paris:—"Si quis comitum vel baronum nostrorum, five aliorum tenentium de nobis in capite per servitium militare, mortuus fuerit, & cum decesserit, hæres suus plenæ ætatis fuerit, & relevium debet, habeat hereditatem suam per antiquum relevium."

What this was, may be seen in the laws of William the Conqueror, &c. Bracton says this fine was called a relief, "quia hereditas, quæ jacens fuit per antecessoris decessum, relevatur in manus hæredum, &c."

A relief is also paid in socage-tenure, or petit serjeanty; where a rent, or other thing, is paid by rendering as much

as the rent or payment reserved. But the manner of taking relief upon socage-tenure is very different from that upon tenure in chivalry. The relief on a knight's fee was 5*l.*, or one-quarter of the supposed value of the land; but a socage-relief is one year's rent or render, payable by the tenant to the lord, be the same either great or small (Litt. § 126.); and, therefore, Bracton (l. 2. c. 37. § 8.) will not allow this to be so properly a relief, but "quædam præstatio loco relevii in recognitionem domini." So, too, the statute 28 Edw. I. c. 1. declares, that a free sokeman shall give no relief, but shall double his rent after the death of his ancestor, according to that which he hath used to pay his lord, and shall not be grieved above measure. Reliefs in knight-service were only payable, if the heir at the death of his ancestor was of full age; but in socage they were due even though the heir was under age, because the lord has no wardship over him. (Litt. § 127.) The statute 12 Car. II. reserves the reliefs incident to socage-tenures; and, therefore, whenever lands in fee-simple are holden by a rent, relief is still due of common right upon the death of a tenant. 3 Lev. 145.

By the custom of Normandy, relief is due for lands held in villinage as well as in fee. By the custom of Paris, relief is not due upon inheritances in the direct line.

The quantity of the relief is very different; there are *single* reliefs, *double* reliefs, &c. The quality, too, is diverse: there are *reliefs of property*, paid by the heir; *reliefs of bail*, or *tutorage*, paid by the guardian for his minor, or by the husband for theiefs of his wife, &c.; *relief of horse and arms*, &c.

By the laws of king Canutus, the relief of an earl, paid to the king, was eight war horses with their bridles and saddles, four cuirasses, four helmets, four swords, four hunting-horses, and a palfrey. The relief of a baron or thane was four horses, &c.

RELIEF, in *Chancery*, denotes an order sued out for the dissolving of contracts, and other acts, on account of their being unreasonable, prejudicial, grievous, or from some other nullity, either *de jure*, or *de facto*.

Minors obtain relief against acts passed in their minority. Majors have relief in cases of enormous damage, deceit, violence, over-reaching, extravagant bargains, &c.

Among the Romanists it is a rule, that the church obtains relief any time, and against all acts passed in its prejudice; no prescription prevailing against it.

RELIEF, *Aid de*. See AID.

RELIEF of a *Hare*, among *Hunters*, is the place where she goes to feed in the evening.

RELIEF, in *Sculpture*. See RELIEVO.

RELIEVE, in the *Military Sense*. To relieve, is to take the post of another-body. Hence, to relieve the guard, to relieve the trenches, &c. is to bring fresh men upon the guard, or to the trenches, and to send those to rest who have been upon duty before. They also say, relieve a sentinel, which is generally done every two hours, by a corporal who attends the relief; relieve the steersman, &c.

To relieve a place that is besieged, is to furnish it, with a supply of men, provisions, ammunition, &c.

RELIEVER, in *Artillery*, is an iron ring fixed to a handle by means of a socket, so as to be at right angles to it. It serves to disengage the first searcher of a gun, when any of its points are retained in a hole, and cannot be got out otherwise.

RELIEVING TACKLES, in a *Ship*, are two strong tackles, used to prevent a ship from overturning on the careen, and to assist in bringing her upright after that operation is completed. The relieving tackles are furnished

with two strong *guys*, or pendants, by which their efforts are communicated, under the ship's bottom, to the opposite side, where the ends of the guys are attached to the lower gun-ports. The other ends of the tackles are hooked to the wharf or pontoon, by which the vessel is careened. Thus, if a ship is first to be laid down on the larboard side, which is nearest the wharf, the relieving tackles are passed under her bottom from the said wharf, and attached to the starboard side, by which they will restrain her from falling lower than is necessary. Falconer.

RELIEVING Tackle, is also a name given to the train tackles of a gun-carriage.

RELIEVO, or RELIEF, *Imbossment*, is applied to a figure which projects, or stands out prominent, from the ground or plane on which it is formed, whether that figure be cut with the chissel, moulded, or cast. There are three kinds of relievo; *viz. alto, basso, and demi-relievo.*

RELIEVO, *Alto, haut relief, or high relievo*, is when the figure is formed after nature, and projects as much as the life.

RELIEVO, *Basso, bas relief, or low relievo*, is when the work is but raised a little from its ground, as we see in medals, and in the frontispieces or buildings, particularly the histories, festoons, foliage, and other ornaments in friezes. See *BASSO Relievo*.

RELIEVO, *Demi*, is when one-half of the figure rises from the plane, *i. e.* when the body of a figure seems cut in two, and one-half is clapped on a ground. When in a basso relievo there are some parts that stand clear out, detached from the rest, the work is called a *demi-basse*.

RELIEVO, in *Architecture*, denotes the fall or projecture of any ornament.

This, Daviler observes, is always to be proportioned to the magnitude of the building it adorns, and the distance at which it is to be viewed.

If the work be insulate, and terminated on all sides, it is called a *figure in relievo*, or a *round embossment*. Such are statues, acroters, &c.

RELIEVO, in *Painting*, denotes the degree of force or boldness by which a figure seems, at a due distance, to stand out from the ground of the painting, as if really imbossed.

The relievo depends much on the depth of the shadow, and the strength of the light; or on the light of the different colours bordering on one another; and particularly on the difference of the colour of the figure from that of the ground.

When the light is well chosen, to make the nearest parts of figures advance; and well diffused on the masses, still diminishing insensibly, and terminating in a large specious shadow, brought off insensibly; the relievo is said to be *bold*, and the *claire obscure, well understood*.

RELIGION, RELIGIO, that worship or homage that is due to God, considered as Creator, Preserver, and, with Christians, as Redeemer of the world.

The foundation of all religion is, that there is a God; and that he requires some acknowledgment and service from his creatures.

Accordingly, religion, in the true meaning of the term, necessarily supposes and includes an intercourse between God and man; *i. e.* on the part of God discoveries and manifestations of himself and his perfections, and of his will with regard to the duties which he requires; and on the part of man, a capacity and readiness to receive and improve those discoveries, and to conform to all the significations of the divine will. For it is an undeniable principle, that whatsoever plainly appeareth to be the mind and

will of God, whatever be the way in which we obtain the knowledge of it, we are indispensably obliged to observe. And as there are two ways by which God may be supposed to manifest himself and his will to mankind, *viz.* by his works and by his word, religion has been usually distributed into *natural* and *revealed*. These are not two kinds of religion, essentially different, much less contrary or contradictory to each other, because they both have God for their object, and proceed from him; nor are they altogether the same, and differing merely in the mode of their communication. Although all true revealed religion must be consistent with, and in no respect contrary to, the clear light of nature and reason, yet it may discover and reveal several things pertaining to truth and duty, which that light, if left to itself, could not have discovered at all, or not with sufficient clearness and certainty. These should not be opposed to one another; nor is the one of them designed to exclude the other.

RELIGION, *Natural*, has been taken in different acceptations. Some understand by it every thing in religion, with regard to truth and duty, which, when once discovered, may be clearly shewn to have a real foundation in the nature and relations of things, and which unprejudiced reason will approve, when fairly proposed, and let in a proper light. Accordingly some Christian philosophers and divines have comprehended under their scheme or system of natural religion, a considerable part of what is contained in the scripture revelation, *e. gr.* the important truths and principles relating to the existence, the unity, and attributes of God, his governing providence and moral administration, the worship that is due to him, the law that is given to mankind; or the whole of moral duty in its just extent, as relating to God, our neighbours, and ourselves, the rewards and punishments of another state, and other articles nearly connected with these, and dependent upon them. Having taken great pains to shew, that all this is perfectly agreeable to sound reason, and founded in the nature of things, they have honoured the whole with the name of *natural religion*. None can hesitate to allow, that it is a real and great service to religion to shew, that the main principles and duties of it are what reason must approve; and those are unquestionably entitled to praise, who have undertaken to demonstrate this with great clearness and force of argument. But it does not follow that, because these things, when once clearly discovered, may be proved agreeable to reason, and to have a real foundation in the nature of things, reason alone, in the present state of mankind, if left to itself, without higher assistance, would merely, by its own force, have discovered all of them, with their genuine consequences, and have applied them to their proper uses, for directing men in the true knowledge and practice of religion. Many things, says Mr. Locke, in his "Reasonableness of Christianity," are taken for unquestionable truths, and easily demonstrable, without considering how long we might have been in doubt or ignorance respecting them, if revelation had been silent. Native and original truth is not so easily wrought out of the mine, as we who have it ready dug and fashioned to our hands, are apt to imagine. To the same purpose Dr. Clarke observes, (*Disc. on Nat. and Rev. Religion*), that it is one thing to see, that these rules of life, which are before-hand plainly and particularly laid before us, are perfectly agreeable to reason, and another thing to find out these rules merely by the light of reason, without their having been first otherwise made known. Accordingly some able and strenuous assertors of natural religion, or the law of nature, though they contend that it is founded in the nature of things,

RELIGION.

things, and agreeable to right reason, derive the promulgation of it from divine revelation. Hence it may be concluded, that natural religion, or the *LAW of Nature* (which see), is not so called, because it was originally discovered by natural reason, but because, when once made known, it is what the reason of mankind, duly exercised, approves, as founded in truth and nature.

Natural religion, in the sense now explained, is very consistent with the supposition of an extraordinary divine revelation, for the purpose of discovering and promulgating it at first, and also of re-establishing and confirming it, when, through the corruption of mankind, the important principles and duties of it were sunk into such darkness, and so confounded with pernicious errors, that an extraordinary assistance was necessary to recover men to the right knowledge and practice of it.

Natural religion is understood by others in a sense which is absolutely exclusive of all extraordinary revelation, and in direct opposition to it. By natural religion, they mean that religion which men discover by the sole exercise of their natural faculties and powers, without any other or higher assistance. These persons discard all pretences to extraordinary revelation, as the effects of enthusiasm or imposture. It is in this sense, that those who call themselves *DEISTS* (see that article) understand natural religion, which they highly extol as the only true religion, the only discovery of truth and duty upon which we may safely depend; and which comprehends the whole of what is necessary to be known and done, in order to our obtaining the favour of God, and attaining to true happiness. But those who take natural religion in this sense entertain different opinions of the subject, and express their sentiments variously. The ablest advocates for natural religion, as opposed to revelation, maintain, that it is clear and obvious to the whole human race, and that all men have a natural knowledge of it. They argue, that since religion is equally the concern of all mankind, the wisdom and goodness of God require, that it should be actually known to all. To this purpose is the reasoning of lord Herbert, who alleges, that God hath imprinted on the minds of all men innate ideas of the main principles of religion and morality. Tindal also, and the author of "*Christianity as old as the Creation*," argue in a similar manner: the former asserts, that this clear universal light that shines into the minds of all men cannot be made clear to any man by an external extraordinary revelation: with the latter it is a kind of fundamental principle, that the law, or religion, of nature was a perfect scheme of religion and morality, fairly drawn on the mind and heart of every man, in such a manner, that it is not possible for any man to mistake it: and he even affirms, that the most illiterate of the human race have naturally and necessarily a clear and intimate perception of the whole of religion and of their duty. Hence it will be easily owned, that there is no need of an extraordinary revelation to teach men what they all naturally and necessarily know. This scheme, however plausible it may at first appear, and though it seems to exhibit a beautiful representation of the dignity of our species, and of the universal goodness of God to the human race, appears to be altogether visionary, when brought to the test of fact and experience: whilst it supposes, that religion, in its true nature and just extent, is naturally known to all men, so that they cannot mistake it, it contradicts the testimony of the authentic history of mankind in all ages, which evinces that they have mistaken religion in its important principles and obligations.

Sensible of the inconveniences of this scheme, others, by natural religion, understand not merely that which is na-

turally and necessarily known to all men, but that which reason, duly exercised and improved, is able, by its own natural force, to discover, without the assistance of any extraordinary revelation. In order to form a just conception of this theory, we might investigate the extent of the powers and abilities of human reason in judging concerning matters of religion, independently of all revelation: but without entering on a speculation of this kind, the disquisition of which would be more curious in the process than satisfactory in the result, we should recur to the surest and plainest mode of judging, which is the examination of the conclusions that may be deduced from fact and experience. Let us then inquire, what hath human reason actually done in this way, by its own force, without any extraordinary assistance? The satisfactory answer to this inquiry cannot be obtained from any systems formed by persons who have lived in ages and countries which have enjoyed the light of divine revelation; since in this case it may reasonably be supposed, that they have borrowed light from revelation, though they are not willing to acknowledge it, or may not themselves be sensible of it. Systems, therefore, that have been drawn up by our modern admirers of natural religion in Christian countries, cannot be alleged in proof of the force of unassisted reason in matters of religion; and the same may be said of those Pagan philosophers who have lived after Christianity had made some progress in the world. Nor can we fairly infer the sufficiency of the light of natural reason, without the aid of revelation, from the systems of the ancient philosophers, lawgivers, and moralists, who lived before the Christian revelation was published; unless it can be shewn, that they themselves derived the religious and moral principles which they taught, solely and entirely from the researches and disquisitions of their own reason, and disclaimed their having had any assistance, with regard to those truths and principles, from tradition or divine instruction. And it is no hard matter to shew, by testimonies from the most celebrated ancients, that this was not the case, nor was it what they assumed to themselves. It is well known, that the most admired philosophers of Greece did not pretend to set up merely on their own stocks, but travelled into Egypt, and different parts of the East, for the purpose of improving their knowledge by conversation with the sages of those countries; who themselves professed to have derived their knowledge, not merely from the disquisitions of their own reason, but from a higher source, from very ancient traditions, to which, for the most part, they assigned a divine original. After all it must be allowed, that the most celebrated and sagacious of the ancient philosophers made pathetic complaints of human darkness and ignorance, and of the great difficulties they experienced in searching after truth. Many of them were sensible of the great need there was of divine instruction and assistance, for enlightening and directing mankind in matters of religion and their duty: so that no argument can be justly drawn from the wise men and philosophers among the ancients, to shew that the knowledge of what is usually called natural religion, in its just extent, is wholly and originally owing to the force of human reason, exclusive of all divine revelation. And perhaps, says the excellent writer whose observations we are now citing, it would not be easy to mention any nations, among whom any true knowledge of religion has been preserved, concerning which we can be assured, that they never had any benefit from the light of divine revelation; and that the principles of religious truth and duty, which were to be found among them, were originally the mere product of natural reason, without any higher assistance. Several things may be observed among them, which

RELIGION.

seem to be the remains of an ancient universal tradition, or primeval religion, derived from the remotest antiquity, and which, probably, had their original source in divine revelation, though in process of time it was greatly altered and corrupted. Leland's Advantage and Necessity of the Christian Revelation, vol. i. § 1.

RELIGION, *Revealed*, is commonly understood to be that knowledge of religion, which was originally communicated from God to men in a way of extraordinary revelation, for instructing them in important religious truth, and directing and engaging them to the practice of their duty. In a general sense, all truth, and the manifestation of it, may be said to come from God, even that which we discover in the ordinary use of those rational faculties which God hath given us. But revealed religion, as distinguished from that which is usually called natural, denotes that knowledge of religion which was originally communicated in an extraordinary and supernatural way. Leland, *ubi supra*. See REVELATION.

The first kind of religion, above-mentioned, or natural religion, flows immediately from the relation between the creature and the Creator; the latter, or revealed religion, does not follow from such a relation, but is superadded from the mere will and pleasure of the Creator.

The first we ordinarily call morality, or ethics; because immediately conversant about the manners and duties of men towards one another; and towards themselves, considered as creatures of that Being. See ETHICS, MORALITY, and MORAL PHILOSOPHY.

The latter we call, by way of eminence, religion, as being the rule of our duty immediately to God himself.

The first supposes a God, a providence, and a future state, of rewards and punishments; the latter likewise supposes an immediate mission from God himself, attested by miracles, &c. See CHRISTIAN Religion.

RELIGION is more particularly used for that special system of faith and worship, which obtains in a particular age, sect, or country, &c.

In this sense we say the Romish religion, the Reformed religion, the religion of the Greeks, the Mahometan religion, the Jewish religion, &c. See JUDAISM, MAHOMETANISM, &c.

The Siamese hold the diversity of religions, *i. e.* the different manners of honouring God, to be pleasing to him; inasmuch as they have all the same object, and all tend to the same end, though by different means. Claude.

This sentiment of these idolaters is doubtless more just than that of our zealots, who hold all but those of their own religion odious to God. The several sects in religion see under their proper articles. See also SECT.

Of the religion of the ruling part of the world, you may find a lively description in a chorus in Seneca's Troas, at the end of the second act, beginning thus: "Verum est, an timidos fabula decipit? umbras corporibus vivere conditis, &c." This, according to Patin, is the religion of princes, and great men, of magistrates, monastic superiors, and even some physicians and philosophers. M. Du Maine, head of the leaguers in France, used to say, that princes have no religion till after they are turned of forty. "Cum numine nobis mors instat, majore facit." Patin. Lett. Choix. 106.

Under this article we are naturally led to discuss the subject of national religion, in its connection with religious establishments. It must appear, on the slightest reflection, that religion has a very considerable influence, not only on the disposition and character of individuals, but on the state of society in general. Accordingly legislators and rulers have often found it one of the most powerful instruments of

civil policy; and the history of almost every country affords numerous instances of its being an excellent ally to the power of the civil magistrate, or the most dangerous rival. By religion we now mean that principle which influences men by the dread of evil or the hope of reward, from unknown and invisible causes; whether the good or the evil be expected to take place in this world or in another; and in this general sense of the term, it comprehends enthusiasm, superstition, and every other species of false religion as well as the true. It would lead us too far, if we attempted to trace the influence of this principle in the more barbarous or more civilized nations of antiquity. Enthusiasm and superstition have been more powerful and more efficacious on many occasions, which history records, than political wisdom in the cabinet, or martial skill and valour in the field. In some cases religion has concurred with the views of the civil magistrate; and in others, it has counteracted them even in favour of the best interests of mankind. It is an observation of Mr. Hume's, that the precious sparks of liberty were kindled and preserved by the Puritans in England, and that it is to this sect, whose principles appear so frivolous, and whose habits so ridiculous, as he somewhat invidiously describes them, that the English owe the whole freedom of their constitution. The assertion, however, is too general. The capital advantage derived from Christianity in this western part of the world, is the total abolition of slavery, in consequence of its raising men's ideas of the importance of the human species. It is a memorable fact, that after the introduction of Christianity into the Roman empire, every law which was made relating to slaves was in their favour, till at last all the subjects of the empire were reckoned equally free. Although, in later times, slavery has been revived and continued, for commercial purposes, in countries calling themselves Christian, we trust that laudable efforts, originating in the liberal sentiments and affections which Christianity inculcates, will be crowned with success, and gradually annihilate this nefarious kind of traffick in every nation of the globe. Christianity, indeed, is almost incompatible with absolute despotic power, both in sovereigns and private persons. The corruptions of Christianity, exemplified in the exorbitant power of the pope, and the superstition of the Popish worship, have been indirectly productive of considerable benefit. The union of the western churches under one supreme pontiff facilitated the intercourse of nations in barbarous ages; and the pomp of the Popish power contributed in no small degree towards preventing the fine arts from being totally lost in the barbarism of Europe, and to their subsequent revival, previously to that of literature and science in this western part of the world. Erroneous notions of religion, and the superstition blended with its purer principles, have been, however, the occasion of the most lamentable evils in the government of states. Beccaria says, in his "Essay on Crimes and Punishments," that more than 100,000 witches have been condemned to die by Christian tribunals. False principles of religion have encouraged men to commit the most horrid crimes; and to inflict tortures both on themselves and others, which cannot be thought of without horror. The historical page of persecution is stained with blood. But it is our present design to sketch out the benefits resulting from religion to civil society, rather than the evils which the perversion of its principles and genuine spirit have produced. It is natural to imagine, that the civil magistrate would take religion under his protection with a view to these benefits; nevertheless, it is much to be lamented that by erroneous notions of its nature and design, and a misapplication of its influence, it has been rendered the in-

RELIGION.

strument of tyranny and oppression. If magistrates and rulers availed themselves of the assistance which religion affords for meliorating the character and condition of the members of the community over which they preside; if they patronized and encouraged the principles and profession of it for the purpose of retraining the profligate and vicious, and of promoting a virtuous conduct with a view to the welfare and prosperity of the state; and if they made use of the mighty powers with which religion furnishes them merely for the purpose of maintaining order and peace in the community to which they belong, and of securing and advancing its true interests; there could be no reason for alarm or complaint. Religion and civil government might unite their efforts for such laudable purposes, and co-operate in promoting them, without any apprehension of danger; but lamentable experience has testified that in too many instances religion has been made subservient to ambition and worldly policy, inasmuch that many persons of just reflection and comprehensive views have dreaded the interference of civil governors in matters of religion. If, in some cases, they have done good, in others their interference has been pernicious, not only to religion, which has been thus corrupted and degraded, but to the civil community itself. Nevertheless the opinion, that it is necessary for the state to prescribe the principles, and to regulate the modes of religion, has been almost universally prevalent.

We are thus led briefly to discuss the subject of national establishments of religion; and that we may do this without prejudice and partiality, we shall state the arguments on both sides of the question, as much as possible in the language of those who oppose, and of those who defend them. Amongst those who have thought freely, and who have written as freely on this subject, we find some who contend against establishments in any degree whatever. They will not allow that religion should receive any support from the state, but insist that it ought to be left entirely to its own operation. There is naturally, they say, no more connection between civil government and religion, than between the former and any thing else that depends upon opinion; less than the business of philosophy or religion. Because these respect the present life, with which civil governors have to do; whereas religion respects the life to come, with which they have nothing to do. However, the conclusiveness of this kind of reasoning seems to be materially affected by our preliminary remarks. Religion, it is said, is a concern that lies out of the proper province of the civil magistrate. Its object is invisible; its principles and affections, which are the springs of moral and religious conduct, as well as its motives and sanctions, are not subject to the direction and controul of secular counsel and power; its seat is the understanding and heart: nor is the external conduct, to which alone the cognizance of the civil magistrate extends, of any importance in a moral view, independently of the internal principles in which it originates, and by which it is guided and governed. Besides, it has been urged that civil rulers have no right to prescribe to the judgment in the province of religion, or to frame and enforce rules of moral conduct, for the observance or violation of which mankind are accountable only to God; nor are they competent or qualified for the exercise of such high powers. And if they cannot controul the faculties of the mind, their influence on the profession and practice, and that outward conformity to modes and rites of a religious nature which they may enforce, without the consent of the judgment and concurrence of the will, are calculated to do much greater harm than good; and to add to the number of hypocrites or martyrs. As the civil magistrate cannot bestow the rewards, nor inflict

the punishments, that are appropriate to religion; and as he cannot estimate the moral worth or demerit of his subjects, he cannot, without culpable presumption, assume, nor without intruding on the province of the supreme and almighty God, exercise the authority of a spiritual and final judge. Civil governors in general, such are their rank and station, the course of their education, and the habits of their lives, are less able than many others of lower condition, but of different views and connections, to decide concerning religious truth, or to determine who are qualified to advise and assist them. Moreover, it has been observed, that neither magistrates nor their ecclesiastical advisers are warranted to establish a standard either of religious faith or moral conduct, to which all the members of a community are required to conform, and from which they are not allowed to deviate without incurring some loss or damage. Such a standard, let it be ever so liberally framed, or ever so mildly enforced, is not likely to be so comprehensive, as to include all the teachers and all the professors of religion, who are entitled to the protection of the state in which their lot is cast. Besides, if such a standard of faith and practice could be devised, those who object to religious establishments on the ground now stated, conceive, that their civil rulers have no right to establish and impose it; and thus to deprive persons, who cannot approve it, of worldly honours and benefits, to which they have naturally an equal claim with others of their fellow-subjects;—a claim, which they do not forfeit by the exercise of their own judgment in the province of religion. It has also been argued, that Christianity, so far from countenancing, rather discourages every kind of religious establishment, that interferes with the right of private judgment. The language of the divine Author of our holy religion is, “Render to Cæsar the things that are Cæsar’s, and to God the things that are God’s;—Search the scriptures;—Call no man master on earth;—My kingdom is not of this world.” And that of his apostles, “Let every man be fully persuaded in his own mind;—Judge ye what I say;” &c. &c. The adversaries of establishments allege, that a national church, constituted by the civil magistrate, and governed by laws enacted by his authority, and the Christian church, founded on the doctrine of Christ and his apostles, are essentially distinct; and they say, that such a church, *e. gr.* the church of England, less exceptionable than many others, which claims and exercises, according to its 20th article, “power to decree rights and ceremonies, and authority in matters of faith,” has, agreeably to the true nature and constitution of the Christian church, no such power and authority; that it is inconsistent with the allegiance which Christians, as the subjects of Jesus Christ, owe to him, the only lawgiver and king in the church; who, as they say, hath expressly commanded that no power of this kind shall ever be claimed, or ever be yielded by any of his followers. In the prosecution of this mode of reasoning, they farther add, that if the church of England hath really this authority and right, the church of Rome had it before, and, as the elder and mother-church, ought to have been obeyed; and consequently the reformation, as it has been called, was a rebellion against superiors, a disobedience to the authority vested in the church, and ought, as such, to be renounced by returning to the church of Rome. They also argue, that this power to order the manner of God’s worship, and to settle articles of faith, is not at all lodged in the bishops or clergy, who are the spiritual pastors and guides in the established church, but entirely in the king and parliament of these realms. So far were the bishops and clergy from having any concern in the first forming our present established church,

RELIGION.

or in ordering its rites and articles of faith, that it was done not only without, but in actual opposition to them. Hence they conclude, that the church of England is, in reality, a parliamentary church; that it is not, properly, an ally, as some have asserted, but a mere creature of the state. It depends entirely upon the acts and authority of parliament for its very essence and frame. The qualifications of its ministers, their power to officiate, the manner in which they are to administer the sacraments, are all limited and prescribed by authority of parliament; and this authority, which at first made, can alone alter and new-make it; can abolish, or add to its articles or rites, according to its pleasure, even though the whole body of bishops and clergy ever so much dislike or protest earnestly against it.

If it be asked, how came the civil magistrate to possess the authority which he exercises in the church of Christ? The objectors to establishments reply, that the subjection to higher powers, and obedience to magistrates, which the scriptures enjoin on Christians, relates only to civil, and not at all to religious matters, for this obvious reason, that the magistrate was at that time every where Pagan. They say, that Christianity is so far from enjoining, that it actually forbids, obedience to civil governors in things of a religious nature. It commands us "to call no man upon earth father or matter" (Matt. xxiii. 8, 9.), *i. e.* to acknowledge no authority or jurisdiction of any in matters of religion, but to remember, that "one, one only is our matter" and lawgiver, even Christ, and that all Christians are brethren: and that, though "the princes of the Gentiles exercise dominion over them, and they who are great exercise authority upon them, yet it shall not," says our Lord, "be so amongst you." (Matt. xx. 25.) Christ's kingdom is not of this world, and of course he is the sole lawgiver, judge, and sovereign in religious matters. (See Matt. xxiii. 8, xxviii. 18, 19. 1 Cor. viii. 6. Ephes. i. 22.) In the church of Christ, it is said, all authority and jurisdiction are vested originally in him, and flow from him, nor can any one lawfully exercise them without a commission from him; but in the church of England, the king, or queen, is "supreme head," possessing "all power to exercise all manner of ecclesiastical jurisdiction, and archbishops, bishops, archdeacons, and other ecclesiastical persons, have no manner of jurisdiction ecclesiastical, but by and under the king's majesty, who hath full power and authority to hear and determine all manner of causes ecclesiastical; and to reform and correct all vice, sin, errors, heresies, enormities, abuses whatsoever, which by any manner of spiritual authority or jurisdiction, ought, or may be lawfully reformed." (26 Hen. VIII. cap. 1. 37 Hen. VIII. cap. 17. 1 Eliz. cap. 1.) At the first establishment of this church under Henry VIII. and Edward VI. all the bishops took out commissions from the crown, for the exercising of their spiritual jurisdiction in these kingdoms, during the king's pleasure only; "and in their commissions acknowledge all sorts of jurisdiction, as well ecclesiastical as civil, to have flowed originally from the regal power, as from a supreme head, and a fountain and spring of all magistracy within his own kingdom." Burnet's Hist. Reform. part ii. Col. p. 92.

Yea, even the power of ordination itself, which is reckoned a peculiar of the episcopal office, the first reformers and founders of this church derived from the king, and exercised only as by authority from him, and during his pleasure. "Thus Cranmer, archbishop of Canterbury, Bonner, bishop of London, &c. took out commissions from the crown, importing, that because the vicegerent (Cromwell, a lay person) could not personally attend the charge in all parts of the kingdom, the king authorises the bishop, in his, (the

king's or perhaps the vicegerent's) stead to ordain, within his diocese, such as he judged worthy of holy orders; to collate to benefices; to give institution; and to execute all other parts of the episcopal authority; and this during the king's pleasure only."

In consequence of this supremacy, the king or queen of this church hath power to excommunicate from, or to readmit into it, independent of, yea, in direct opposition to, all its bishops and clergy. The king or queen revoke, if they please, any spiritual censures of the bishops or archbishops; yea, can suspend, deprive, or even excommunicate, themselves; or can, by their proclamation only, without the least confession, humiliation, or satisfaction for their offence, pardon and restore excommunicated persons, the vilest offenders, to the church's bosom again.

Yea, further, they have power to forbid all preaching for a time; as did king Henry VIII. king Edward VI. queen Mary, and queen Elizabeth; to limit, instruct, and prescribe to the clergy what they shall, and what they shall not preach; as did queen Elizabeth, king James I. king Charles I. king William, &c. Finally, to the king or queen only does it pertain to declare what is heresy, and authoritatively to pronounce what doctrines and tenets are, and what are not, to be censured as such: nor have all the bishops and clergy, assembled in convocation, the least authority to censure any tenet as heretical, if the prince on the throne refuse his consent.

Accordingly, the objectors to religious establishments allege, that in Christ's church, himself is the only sovereign and head; he only hath power to decree ceremonies and rites; to fix terms of communion and authority in points of faith: nor hath any earthly prince power to make laws in his kingdom, which shall bind the conscience of his subjects; or sovereignly to dictate to his servants and ministers what they shall believe, and what they shall preach. Yea, his subjects are expressly commanded and charged to receive nothing as doctrine or parts of religion, which are only commandments of men.

But in the church of England there is another sovereign, lawgiver, supreme head, besides Jesus Christ; an authority which commands things which Christ never commanded, which teaches doctrines he never taught, which enjoins terms of communion, and rites of religious worship, which Christ never enjoined. Hence they conclude, that these two churches are two distinct and quite different societies, framed after different models, consisting of different members, and governed by different officers, statutes, and laws. Whilst the objectors to established forms of worship esteem and reverence the great number of illustrious and excellent persons, both clergy and laity, of which the church of England can boast, they suggest, that the present established forms were drawn up when this kingdom just emerged out of Popish darkness; that in drawing them up special regard was had to the weakness of the people at that time, who could not be all at once entirely brought off from the old ceremonies and forms; and that there are several parts of our liturgy and ecclesiastical constitution, which even many of our bishops and clergy wish to see altered. Schemes have been proposed, and attempts have been made for omitting what is offensive, for correcting what is easily capable of amendment, and for accommodating the doctrine and forms of the established church, to the present advanced state of knowledge, and to the corresponding liberality of the modern professors of religion, both in and out of the church; but they have hitherto been unavailing: and it has been thought, that an exclusive establishment, appropriating to itself distinguished honours and benefits of a secular nature, and exposing those whom

RELIGION.

whom it does not comprehend to privations, both of emolument and honour, has a tendency to discourage every effort for improving its constitution, and enlarging its boundaries. Some have also been of opinion that it restrains freedom of inquiry, embarrasses integrity, and too much disposes the uninstructed and uninformed to intolerance and persecution. From whom, it has been said, is a reform to be expected, but from those who have reason for wishing every thing to continue in statu quo? The dignitaries of the church, whose emoluments induce them to rest satisfied, and the ruling magistrates of the state, who wish things to remain quiet, and the great body of the laity, connected in one way or other with ecclesiastical establishments, cannot be supposed to be very anxious about a change in the constitution of the church: nor will they be at a loss for plausible reasons for resisting any material alteration. The church and the state are so incorporated, that nothing but a revolution, as it has been said, in the latter, would cause any very important amendment in the former. Nevertheless, reformers have maintained, that if the liturgy, clergy, articles, canons, with all the ceremonies and rites of the established church, were entirely vanished from the land; if its immense revenues were applied to ease our heavy taxes, and for the payment of the public debts; and if preachers were paid only by voluntary contributions; the state would not sustain so essential a loss and damage, that it could not thenceforward possibly subsist. Would, say they, the British monarchy be overthrown; our courts of judicature be shut up; the courts of law be stopped; parliaments no more meet; and commerce and trade stagnate, because the national church was no more? On the contrary, however great the convulsion might be, the government, both civil and military, might remain the very same. A timely reformation, however, would, as they imagine, prevent its total destruction, and contribute to its permanence and prosperity.

Some notice should here be taken of the learned Warburton's famous argument in favour of an established church. The church, says this prelate, has, by contract or alliance, resigned her supremacy in matters ecclesiastical, and her independency, to the state. In consequence of this, the state hath drawn up for her articles of faith, and forms of public worship, which it requires the church to subscribe and use. This alliance is a mere phantom, created by the warm imagination of the paradoxical bishop, whose ingenuity and learning have not been sufficient to render it popular, even among the most zealous advocates of religious establishments. Neither our history nor our laws know any thing at all of it. The nature of our constitution utterly disowns it; and avows the church to be not an ally, but a subject to the state. An alliance supposes independency in the powers between which it subsists. But it is needless to enlarge on this topic.

Whilst it is allowed that religion has an influence on the conduct of men in this life, it is pleaded, on the other hand, that this beneficial influence of religion is promoted in all denominations of Christians, and as much in those which are reprobated by the state as in those which are encouraged by it. It has been also said, that the subject of religion is so interesting to the generality of mankind, that if government did not interfere, the contention about it would be so violent, that the public peace could not be preserved. To this argument in favour of establishments, it has been replied, that these contentions are much increased by the favour shewn to one mode of religion, and the opprobrium which is consequently thrown on the rest; and that, where temporal interest is not concerned, mere opinions will not occasion any

differences at which government need to be alarmed. Christianity was introduced and established, and subsisted for about three hundred years, without any favour or protection from the governing powers; and the example of America, in some provinces of which there is, strictly speaking, no establishment of religion, and in which numerous forms of religion are openly professed, serves to shew, that the want of an establishment is attended with no danger to the state. It is farther objected, that the state, by undertaking the care of religion, the truth and utility of which will, under providence, ensure its permanence, has taken upon itself a great, dangerous, and unnecessary burden; and from its jealousy of sectaries, often deprives itself of the services of some of its best and most able subjects; and at some times it has been induced to persecute and destroy them, because if they were left free, and even suffered to live, it was apprehended their principles might spread to the risk of the establishment. To the national establishment of our own country, the enlightened advocates of which abhor and discountenance intolerance and persecution, it has been objected, that it deprives the people of the choice of their own teachers and pastors; that it imposes subscription to creeds of doubtful evidence, and the observance of forms of questionable utility, on its own ministers; that it renders the support of them burdensome to those who avail themselves of their labours, and to others who derive no benefit from them; and that it excludes by obnoxious statutes a considerable class of loyal subjects from offices which they are competent to discharge, as well as emoluments and honours of which they have a right to participate. See DISSENTERS, SUBSCRIPTION, TEST, and TYTHES.

We now proceed to state the arguments that have been urged in favour of national establishments of religion; and we shall here avail ourselves of the reasoning of an excellent writer, who has done ample justice to the subject, and who, at the same time, has discussed it with a liberality and moderation, which have a tendency to conciliate those whose sentiments may be different from his own. "A religious establishment," he says, "is no part of Christianity; it is only the means of inculcating it." It cannot be proved, that any form of church government has been laid down in the Christiana, as it had been in the Jewish scriptures, with a view of fixing a constitution for succeeding ages; and which constitution, consequently, the disciples of Christ would, every where, and at all times, by the very law of their religion, be obliged to adopt. Certainly no command for this purpose was delivered by Christ himself; and though the apostles ordained bishops and presbyters among their first converts, and appointed also deacons and deaconesses, investing them with functions different from any that now subsist, such offices were at first erected in the Christian church, as the good order, the instruction, and the exigencies of the society at that time required, without any declared design of regulating the appointment, authority, or distinction of Christian ministers under future circumstances. After this concession, our author founds the authority of a church establishment in its utility; and in judging of the comparative excellence of different establishments, he suggests, that the single view, under which we ought to consider any of them, is that of "a scheme of instruction," and the single end we ought to propose by them is, "the preservation and communication of religious knowledge." Every other idea, and every other end that have been mixed with this, as the making of the church an engine, or even an ally of the state; converting it into the means of strengthening, or of diffusing influence; or regarding it as a support of regal, in opposition to popular forms of government, have served only

to debase the institution, and to introduce into it numerous corruptions and abuses. The notion, says our author, of a religious establishment comprehends three things, a clergy, or order of men secluded from other professions to attend upon the offices of religion; a legal provision for the maintenance of the clergy; and the confining of that provision to the teachers of a particular sect of Christians. Without these, there exists no national religion, or established church, according to the sense which these terms are usually made to convey. He, therefore, who would defend ecclesiastical establishments, must shew the separate utility of these three essential parts of their constitution. Under the first head he maintains, that the knowledge and profession of Christianity cannot be maintained in a country without a class of men set apart by public authority to the study and teaching of religion, and to the conducting of public worship; and that for these purposes they should be precluded from other employments; and that of course they ought to derive a maintenance from their own. If they depended for this maintenance upon the voluntary contributions of their hearers, he is of opinion, that few would ultimately contribute any thing at all. To the consideration of the difficulty with which congregations would be established and upheld upon the *voluntary* plan, he adds, that of the condition of those who are to officiate in them. Preaching, he thinks, would in this case become a kind of begging; and the preacher, being at the mercy of his audience, would be obliged to adapt his doctrines, and also his style and manner of preaching, to the pleasure of a capricious multitude; and to live in constant bondage to tyrannical and insolent directors; which he could not do without a sacrifice of principle, and a depravation of character. Admitting these circumstances to be fairly stated, which perhaps an objector would reluctantly allow, Dr. Paley concludes, that a legal provision for the clergy, compulsory upon those who contribute to it, is expedient; and then proceeds to inquire, whether this provision should be confined to one sect of Christians, or extended indifferently to all. This question, it should be recollected, *can* never offer itself where the people are agreed in their religious opinions, and *ought* never to arise, where a system of doctrines and worship may be so framed as to comprehend their disagreements, and which might satisfy all by uniting all in the articles of their common faith, and in a mode of divine worship that omits every subject of controversy or offence. Where such a comprehension is practicable, the comprehending religion ought to be made that of the state. But where this comprehension is impracticable, and separate congregations and different sects must continue in the country, the question fairly recurs, whether, under such circumstances, the laws ought to establish one sect in preference to the rest; that is, whether they ought to confer the provision assigned to the maintenance of religion upon the teachers of one system of doctrines alone. This question is intimately connected with, and in a great measure dependent upon, another; and that is, in what way, or by whom, ought the ministers of religion to be appointed? In that species of patronage which subsists in this country, and which allows private individuals to nominate teachers of religion for districts and congregations, to which they are absolute strangers, some test should be proposed to the persons nominated, in order to prevent that discordancy of religious opinions that might otherwise arise between the several teachers and their respective congregations. The requisition of subscription, or any other test by which the national religion is guarded, may be considered merely as a restriction upon the exercise of private patronage. Wherefore, therefore, this constitution of patronage is adopted,

a national religion, or the legal preference of one particular religion to all others, must almost necessarily accompany it. If we suppose that the appointment of the minister of religion was in every parish left to the choice of the parishioners, might not this choice be safely exercised, without its being limited to the teachers of any particular sect? The effect, says our author, of such a liberty must be, that a Papist, or a Presbyterian, a Methodist, a Moravian, or an Anabaptist, would successively gain possession of the pulpit, according as a majority of the party happened at each election to prevail; and on every choice, it is apprehended, that violent conflicts would be renewed, and bitter animosities be revived. If the state appoint the ministers of religion, this constitution will differ little from the establishment of a national religion: for the state would undoubtedly appoint only those whose religious opinions, or rather whose religious denomination, agree with its own; unless it be thought that religious liberty would derive any advantage from transferring the choice of the national religion from the legislature of the country to the magistrate who administers the executive government. The only plan which seems to render the legal maintenance of a clergy practicable, without the legal preference of one sect of Christians to another, is that of an experiment which has been attempted (and which is said to have succeeded) in some of the new states of North America. The nature of the plan is thus described. A tax is levied upon the inhabitants for the general support of religion: the collector of the tax goes round with a register in his hand, in which are inserted, at the head of so many distinct columns, the names of the several religious sects that are professed in the country. The person who is called upon for the assessment, as soon as he has paid his quota, subscribes his name in which of the columns he pleases; and the amount of what is collected in each column is paid over to the minister of that denomination. In this scheme it is not left to the option of the subject, whether he will contribute, or how much he shall contribute, to the maintenance of a Christian minister: it is only referred to his choice to determine by what sect his contribution shall be received. The above arrangement, says Paley, is undoubtedly the best that has been proposed upon this principle; it bears the appearance of liberality and justice; and it may contain some solid advantages. But our author thinks that its inconveniences will be found to overbalance all its recommendations. It is scarcely compatible with the first requisite in an ecclesiastical establishment, which is the division of the country into parishes of a commodious extent. If the parishes be small, and ministers of every denomination be stationed in each, which the plan seems to suppose, the expence of their maintenance will become too burdensome a charge for the country to support. If, for reducing the expence, the districts be enlarged, the place of assembling will, in some cases, be too far removed from the residence of the persons who ought to resort to it. Besides, if the pecuniary success of the different teachers of religion be made to depend upon the number and wealth of their respective followers, this would naturally generate strifes and indecent jealousies amongst them, as well as produce a polemical and profelyting spirit, founded in or mixed with views of private gain; which would both deprave the principles of the clergy, and distract the country with endless contentions.

If it be expedient, says our author, to establish a national religion, that is, one sect in preference to all others, some *test*, by which the teacher of that sect may be distinguished from the teachers of different sects, appears to be an indispensable consequence. The existence of such an establish-
ment

ment supposes it: the very notion of a national religion includes that of a test. But the necessity of a test has furnished to almost every church a pretence for extending, multiplying, and continuing such tests beyond what the occasion justified. For though some purposes of order and tranquillity may be answered by the establishment of creeds and confessions, yet they are at all times attended with serious inconveniences. They check inquiry; they violate liberty; they ensnare the consciences of the clergy, by holding out temptations to prevarication; and in process of time, they contradict the opinions of the church, whose doctrines they profess to contain; and they often perpetuate the proscription of sects and tenets, from which any danger has long ceased to be apprehended. Although tests and subscriptions may not be abolished, they should be made as easy and simple as possible. They should be adapted from time to time to the varying sentiments and circumstances of the church in which they are received; nor should they at any time advance one step farther than some subsisting necessity requires. Promises of conformity to the rites, liturgy, and offices of the church, if sufficient to prevent confusion in the celebration of divine worship, should be accepted in the place of stricter subscriptions. If any agreements, not to preach certain doctrines, nor to revive certain controversies, denominated articles of *peace*, would exclude indecent altercations amongst the national clergy, and also secure to the public teaching of religion as much of uniformity and quiet as is necessary to edification; then confessions of faith ought to be converted into articles of peace. In a word, it ought to be held, says Dr. Paley, a sufficient reason for relaxing the terms of subscription, or for dropping any or all of the articles to be subscribed, that no present necessity requires greater strictness.

It is a question that has been long agitated in the reformed churches of Christendom, whether a parity amongst the clergy, or a distinction of orders in the ministry, be more conducive to the general ends of the institution? Our author is inclined to the latter alternative, for reasons which he has stated.

In discussing the subject of a national establishment of religion, the right of the civil magistrate to interfere at all in matters of religion offers itself to consideration; and although this right may be acknowledged whilst he is employed solely in providing means of public instruction, it may be questioned whether he should inflict penalties, and impose restraints or incapacities on the account of religious distinctions. Our author, deducing the authority of civil government from the will of God, and inferring that will from public expediency alone, concludes that the jurisdiction of the magistrate is limited by no consideration but that of general utility; or that whatever be the subject demanding regulation, it is lawful for him to interfere, whenever his interference, in its general tendency, appears to be conducive to the common interest. Our author conceives, that there is nothing in the nature of religion, as *such*, which exempts it from the authority of the legislator, when the safety or welfare of the community requires his interposition. To the objection, that religion, pertaining to the interests of a life to come, lies beyond the province of the civil government, the office of which is confined to the affairs of this life, Dr. Paley replies, that when the laws interfere even in religion, they interfere only with temporals; their effects terminate, their power operates only upon those rights and interests, which confessedly belong to their disposal. He proceeds to observe, probably without satisfying the objector, "that the acts of the legislator, the edicts of the

prince, the sentence of the judge, cannot affect my salvation; nor do they, without the most absurd arrogance, pretend to any such power: but they may deprive me of liberty, property, and even of life itself, on account of my religion; and however I may complain of the injustice of the sentence, by which I am condemned, I cannot allege that the magistrate has transgressed the boundaries of his jurisdiction; because the property, the liberty, and the life of the subject, may be taken away by the authority of the laws, for any reason, which, in the judgment of the legislature, renders such a measure necessary to the common welfare. Moreover, as the precepts of religion may regulate all the offices of life, or may be so construed as to extend to all, the exemption of religion from the control of human laws might afford a plea, which would exclude civil government from every authority over the conduct of its subjects. Religious liberty is like civil liberty, not an immunity from restraint, but the being restrained by no law, but what in a greater degree conduces to the public welfare."

By way of qualifying this reasoning, which may be thought exceptionable, Dr. Paley observes, that "still it is right to obey God rather than man."—"When human laws interpose their direction in matters of religion, by dictating, for example, the object or the mode of divine worship; by prohibiting the profession of some articles of faith, and by executing that of others; they are liable to clash with what private persons believe to be already settled by precepts of revelation, or to contradict what God himself, they think, hath declared to be true. In this case, on whichever side the mistake lies, or whatever plea the state may allege to justify its edict, the subject can have none to excuse his compliance. The same consideration also points out the distinction, as to the authority of the state between temporals and spirituals. The magistrate is not to be obeyed in temporals more than in spirituals, where a repugnance is perceived between his commands, and any credited manifestations of the divine will; but such repugnancies are much less likely to arise in one case than in the other." The general proposition laid down by our author is as follows: "That it is lawful for the magistrate, to interfere in the affairs of religion, whenever his interference appears to him to conduce, by its general tendency, to the public happiness." To others this proposition will appear to be in many respects exceptionable. The magistrate of course is to be the judge, what are the occasions in which he may interfere; and these occasions will occur whenever he pleases. Dr. Paley has therefore endeavoured to guard it against misapprehension and misapplication. Having stated, that it is the *general* tendency of the measure, or, in other words, the effects which would arise from the measure being *generally* adopted, that fixes upon it the character of rectitude or injustice, he then proceeds to inquire what is the degree and the sort of interference of secular laws in matters of religion, which are likely to be beneficial to the public happiness. In settling this point he premises two maxims; the first is, that any form of Christianity is better than no religion at all; and the second is, that of different systems of faith, that is the best which is the truest. From the first proposition it is inferred, that when the state enables its subjects to learn *some* form of Christianity by distributing teachers of a religious system throughout the country, and by providing for the maintenance of these teachers at the public expence; that is, when the *laws* establish a national religion, they exercise a power and interference, which are likely, in their general tendency, to promote the interest of mankind:

But after the right of the magistrate to establish a particular religion has been, upon this principle, admitted; a doubt arises, whether the religion he ought to establish be that which he himself professes, or that which he observes to prevail amongst the majority of the people. Assuming it to be an equal chance, which of the two religions, that of the magistrate or that of the people, contains more of truth, it becomes a consideration of some importance, to which arrangement we may attach the greater efficacy; that of an order of men appointed to teach the people their own religion, or to convert them to another; and as in our author's opinion the advantage lies on the side of the former scheme, it becomes the duty of the magistrate, in the choice of the religion which he establishes, to consult the faith of the nation rather than his own. For our author's reasoning on other topics connected with a national establishment of religion, we refer to the articles SUBSCRIPTION, TEST, and TOLERATION. He closes the discussion of the general subject with the following summary of his argument: the result of our examination of those general tendencies, by which every interference of civil government in matters of religion ought to be tried, is this: "That a comprehensive national religion, guarded by a few articles of peace, and conformity, together with a legal provision for the clergy of that religion; and with a complete toleration of all dissenters from the established church, without any other limitation or exception, than what arises from the conjunction of dangerous political dispositions with certain religious tenets, appears to be, not only the most just and liberal, but the wisest and safest system, which a state can adopt: inasmuch as it unites the several perfections, which a religious constitution ought to aim at—liberty of conscience, with means of instruction; the progress of truth, with the peace of society; the right of private judgment, with the care of the public safety." Paley's Principles of Moral and Political Philosophy, vol. ii. ch. 10.

In most countries where religion is established, it is that of the majority of the people; and on this principle the writers in defence of ecclesiastical establishments vindicate them. But in a part of the united kingdom of Great Britain, viz. in Ireland, we have a remarkable exception to this rule. There the established religion is not that of the majority, but of a small minority of the people. Ever since the reformation the members of the church of England have kept possession of the tithes of the whole island, where they have long despaired of bringing the people over to that religion for which they pay so dear.

In connection with the national establishment of religion we shall here remark, that in this country the care which government takes of religion extends itself to the business of education, confining the universities, which are supported by the national funds, to the education of the members of the church of England, and rigorously excluding all sectaries, either by requiring subscription to the thirty-nine articles at the time of matriculation, or of taking certain degrees, or obliging the students to attend the service of the established church, and to declare that they are *bona fide* members of it.

Among the offences against religion enumerated by judge Blackstone, and punishable by the laws of England, are *apostacy* and *heresy*, which see respectively; and also those which affect the established church. These latter are either positive or negative; positive by reviling its ordinances, or negative, by non-conformity to its worship. See REVILING, &c. COMMON Prayer, NON-CONFORMISTS, DISSIDENTS,

PAPISTS, and POPERY. See also BLASPHEMY, PROFANENESS, CONJURATION and WITCHCRAFT, Religious IMPOSTORS, SUNDAY, False PROPHECIES, DRUNKENNESS, LEWDNESS, and SIMONY.

RELIGION, again, is applied to a military order, consisting of knights who live under some certain rule, &c.

In this sense we say, the religion of Malta, &c. See MALTA.

RELIGION is sometimes also used for a convent. Thus, we say, there are religions of men, *i. e.* monks; religions of women, *i. e.* nuns.

RELIGION, *The*, used absolutely, denotes the Reformed in France. Thus, they say, d'Ablancourt and Dacier were of the religion. See HUGUENOTS.

RELIGIOUS, in a general sense, something that relates to religion.

We say, a religious life, religious society, &c. Churches and church-yards are religious places. A religious war is also called a *croisade*; which see.

RELIGIOUS is more particularly used for a person engaged by solemn vows to the monastic life; or a person shut up in a monastery, to lead a life of devotion and austerity, under some rule or institution.

The male religious we popularly call *monks* and *friars*; the female, *nuns* and *canonesses*. See CANON, MONK, NUN, &c.

M. Nicole observes, that some domestic chagrins, and a certain pride, which leads people to abscond when they cannot make a figure to their mind, make as many religious as real piety. He adds, that a girl must often be made a religious for no other reason, but because she cannot be married answerable to her condition.

Great influence, however, may be attributed to enthusiasm and superstition, and to those mistaken notions of duty and of perfection of character, which have often originated in these sources, and which have produced effect on honest minds of a peculiar temperament and disposition. Whilst no kind of argument can justify this retirement from the world, and total seclusion from the occupations and pleasures of social life, it would manifest a want of candour as well as ignorance of human nature indiscriminately to condemn all who have devoted themselves to such a kind of indolent and useless life.

A religious cannot make any will. By the council of Trent, a religious may reclaim his vows within five years.

Anciently the religious were all laymen, and it was even prohibited them to take up orders. In 1557, the parliament of Paris made a difficulty of receiving a bishop of Laon to the oath of a duke and peer, by reason of his being a religious: yet a religious, being promoted to a bishopric, is thenceforth secularized or dispensed from the observation of his rule.

In ancient deeds and conveyances of lands, we often find the seller restrained from giving or alienating it, *viris religiosis, vel Judais*, to religious, or to Jews; to the end the land might not fall into *mortmain*; which see.

In a memorial directed by king John to his viscounts, they are ordered to proclaim through their respective counties, that nobody, as they love their bodies and cattle, injure the religious or clerks, either in word or deed, on penalty of being hanged up on the next oak. "Nulli, sicut diligunt corpora et catalla sua, malum faciant vel dicant viris religiosis vel clericis. Si quem inde attingere possimus, ad proximam queream cum suspendi faciemus."

RELIGIOUS Houses, denote houses set apart for religious purposes,

purposes, such as monasteries, churches, hospitals, and all other places where charity is extended to the relief of the poor and orphans, or for the use or exercise of religion. See "Notitia Monastica," or "A short History of the religious Houses in England and Wales," by Tanner, 8vo.; in which, according to the alphabetical order of counties, is accurately given a full account of the founders, the time of foundation, tutelar saints, the order, the value, and the dissolution; with reference to printed authors and MSS. which preserve any memoirs relating to each house; with a preface of the institution of religious orders. Cowel.

RELIGIOUS *Impostors*. See IMPOSTORS.

RELIGIOUS *Order*. See ORDER.

Most military orders pretend likewise to be religious; as those of Malta, who make vows, &c. See MALTA.

RELINQUISHMENT, in *Law*, is a forsaking, abandoning, or giving over. It hath been adjudged, that a person may relinquish an ill demand in a declaration, &c. and have judgment for that which is well-demanded.

RELIQUA, the remainder or debt, which a person finds himself debtor in, upon the balancing or liquidating an account.

Hence *reliquitary*, the debtor of a reliqua; as also a person who only pays piece-meal.

The term reliqua is pure Latin.

RELIQUÆ, RELICS, in *Antiquity*, the ashes and bones of the dead, which remained after burning their bodies; and which they very religiously gathered, and put into urns, and afterwards deposited in tombs. See RELICS.

RELIQUARY, a shrine or casket, in which the relics of a dead saint are kept.

RELIQUE. See RELICS.

RELIQUIA, in *Natural History*, a term used to express the fossil remains of certain substances found in different parts of the earth. In the article PETRIFICATIONS we have given the Linnæan division of the fifth class of minerals, and a pretty full description of the eight genera into which it is divided. In this place we shall present our readers with a very brief view of Mr. Martin's "Systema Reliquiorum." He considers the regnum fossilis, or fossil kingdom, to be divided into five classes, *viz.*

- I. Reliquia, or fossil remains from animals or plants.
- II. Terræ, earths.
- III. Salia, salts.
- IV. Inflammabilia, inflammable substances.
- V. Metalla, metallic substances.

The reliqua he divides into two orders, *viz.* animal and vegetable remains: of the former he gives eight genera; of the latter only one genus, which are as follow:

Order I. RELIQUIA ANIMALIA.

Innata.

- Genus 1. Mammodolithus, or remains of Mammalia.
2. Ornitholithus, - - Birds.
 3. Amphibiolithus, - - Amphibia.
 4. Ichthyolithus, - - Fishes.
 5. Entholithus, - - Insects.
 6. Helmintholithus, of the parts of worms not fabricated.

Fabricata.

7. Conchyliolithus, or remains of Testacea.
8. Erismatolithus, of fulciments, or fabricated supports of worms.

Order II. RELIQUIA VEGETALIA.

9. Phytolithus, the remains of Plants.

Mr. Martin has given certain fundamental principles, on which he conceives the study of reliquia may be scientifically conducted: these are as follow.

1. All natural bodies without life found on or beneath the surface of the earth, and which are not susceptible of putrefaction, belong to the fossil kingdom, and are either reliquia or minerals. Fossils are usually denominated "bodies destitute of an organic structure:" now though it be admitted that all fossils are, according to the common acceptation of the term, unorganized, they are not destitute of the structure which distinguishes an organized body. This being admitted, it follows that a line must be drawn between animal and vegetable matter recently buried in the earth, and which has acquired a genuine fossil character. This line will depend perhaps on putrefaction, to which even organic substances, after they have become fossil, are no longer subject.

2. An organic structure, whether of a plant or animal, is the essence of an extraneous fossil or reliquium. By this alone it is characterized, or distinguished from a mineral.

3. It is the organic form alone on which the arrangement of reliquia must be founded. Every system of natural bodies should assume for its basis but one principle, and this should be drawn from the most essential characteristics of the bodies under arrangement. It is on this account the form is pointed out as furnishing the only genuine principle, on which the classification of reliquia can be established.

4. The primary divisions of the arrangement, *viz.* orders, genera, &c. should agree with such natural divisions of plants and animals as are determinable by the form of the fossil subjects.

5. The specific differences in reliquia depend on the specific differences of form in the original bodies. One species of plant or animal can give but one real or genuine species of extraneous fossil. For if the essence of the reliquium be an organic form, its other affections, arising from substance, mode, and soil, are accidental, and cannot be used as specific distinctions, which must always depend on something essential to the body which we wish to discriminate. *Form*, therefore, must furnish specific differences of reliquia, and it of course follows that there will be as many genuine species of reliquia, as there are genuine specific forms in the animal and vegetable prototypes or originals: and that the number of fossil species are not increased by a separation of parts, or other accidental circumstances to which the original bodies may have been subjected during their change into fossils.

6. Specific distinctions of reliquia being founded only on the organic form, it follows, that their geological and mineralogical affections, with their modal diversities, merely characterize specimens.

7. The specific descriptions of reliquia are to be given according to the principles of botany and zoology. Those of the specimens, according to the principles of mineralogy and geology. The *essential* form of the reliquium must be distinguished from the *accidental*, that is, the form of the original body, from that which has arisen in the fossil from the mode of mineralization, the constituent substance, and the soil of the specimen.

8. The nomenclature of reliquia should manifest the extent of the present state of knowledge with respect to the original bodies.

To what has been said, we shall add an account of our author's "Delineations of Reliquia."

The leading parts in the delineation of a reliquium are

the specific character or diagnosis, and the general description.

The *specific character* contains the marks that distinguish the species to which they belong, from all others in the same genus. Specific characters of reliquia should be so constructed as to distinguish permanent from temporary species; and those whose originals have not, as yet, been discovered. The specific character of the recent species of plants or animals frequently depends on parts often or constantly wanting in the fossil subject. When that is the case, another diagnosis must be given to distinguish the reliquium; that of the recent species being marked as a parenthesis. The generic and trivial names are prefixed to the specific character. And, generally, the name of the family, or subdivision of the genus to which the reliquium belongs: after which is to be detailed in distinct classes, 1. The synonyms or names by which the species has been distinguished by authors, with references to the figures given of it. 2. The varieties of the species, with their synonyms. 3. The vernacular name. 4. The mode or state in which the reliquium is found. 5. Its soil or geological situation. 6. Its geographic situation, and then the general description.

The description delineates in appropriate terms all the parts constituting the essential form of the reliquium, according to their number, figure, proportion, and situation: it must primarily refer to the original of the reliquium, as no just or perfect delineation of the species can be given, until the nature of its prototype be ascertained.

The terms employed in describing reliquia, which derive their form from the external parts of animals and plants, must be those used by zoologists and botanists of the Linnæan school. But those which derive their form from the internal parts of organic bodies, are to be described in such terms as anatomists would use in distinguishing the same parts in the recent subjects.

As attendant parts to the general description of the reliquium must be given, 1. An enumeration of the specimens which exhibit the various accidental forms under which the species has been found. 2. An enumeration of the various substances which have been observed as constituting the reliquium and its matrix.

Having given this brief account of Mr. Martin's scientific delineations of reliquia, we shall present our readers with the substance of two very interesting communications sent to the Royal Society since the printing of the article *PERRI-FRACTIONS*. Of these, the first is "An Account of some Organic Remains found by Mr. Trimmer, near Brentford, in Middlesex."

"The specimens," says Mr. Trimmer, "have been collected from two fields, not contiguous to each other; therefore, to avoid confusion, I shall take each field separately, first describing the strata as far as they have come within my knowledge, and afterwards I shall speak of the organic remains as they were respectively found in those strata.

"The first field is about half a mile north of the Thames at Kew bridge; its surface is about twenty-five feet above the Thames at low water. The strata here are, first, sandy loam from six to seven feet, the lowest two feet slightly calcareous. Second, sandy gravel, a few inches only in thickness. Third, loam slightly calcareous, from one to five feet: between this and the next stratum, peat frequently intervenes in small patches, of only a few yards wide, and a few inches thick. Fourth, gravel containing water; this stratum varies from two to ten feet in thickness, and is always the deepest in the places covered by peat; in these places the lower part of the stratum becomes an heterogeneous mass of clay, sand, and gravel, and frequently

exhales a disagreeable muddy smell. Fifth, the main stratum of blue clay, which lies under this, extends under London and its vicinity; the average depth of this clay has been ascertained, by wells that have been dug through it, to be about two hundred feet under the surface of the more level lands, and proportionally deeper under the hills, as appears from lord Spencer's well at Wimbledon, which is five hundred and sixty-seven feet deep. This stratum, besides figured fossils, contains pyrites and many detached nodules; at the depth of twenty feet there is a regular stratum of these nodules, some of which are of very considerable size.

"In the first stratum, as far as my observation has extended, no remains of an organized body has ever been found, and as my search has not been very limited, I may venture to say it contains none. In the second stratum, snail-shells, and the shells of river fish, have been found, and a few bones of land animals, but of inconsiderable size, and in such a mutilated state, that it cannot be ascertained to what class they belong. In the third stratum, the horns and bones of the ox, and the horns, bones, and teeth of the deer, have been found, and also, as in the second stratum, snail-shells, and the shells of river-fish. In the fourth stratum were found teeth and bones of both the African and Asiatic elephants, teeth of the hippopotamus, bones, horns, and teeth of the ox.

"A tusk of an elephant measured, as it lay on the ground, nine feet three inches, but, in attempting to remove it, it broke into small pieces. When this stratum dips into the clay, and becomes a mixed mass, as before stated, it is seldom without the remains of animals. In the fifth stratum, namely, the blue clay, the extraneous fossils are entirely marine, with the exception of some specimens of fruit and pieces of petrified wood, the latter of which may be considered as marine, because, when of sufficient size, they are always penetrated by teredines. The other fossils from this stratum are nautili, oysters, pinnæ marinæ, crabs, teeth and bones of fish, and a great variety of small marine shells; this stratum has been penetrated hitherto in this field only to the depth of thirty feet, throughout which the specimens found were dispersed without any regularity.

"The second field is about one mile to the westward of the former, one mile north of the Thames, and a quarter of a mile to the eastward of the river Brent; its height above the Thames, at low water, is about forty feet. The strata are, first, sandy loam, eight or nine feet, in the lowest three feet of which it is slightly calcareous. Second, sand, becoming coarser towards the lowest part, and ending in sandy gravel from three to eight feet. Third, sandy loam highly calcareous, having its upper surface nearly level, but gradually increasing in thickness from a feather-edge to nine feet. Below this are two strata of gravel and clay, as in the other field; but as these strata have been only occasionally penetrated in digging for water, nothing therefore is known with respect to them, but that they exist there.

"In the first stratum, as in the other field, no organic remains have been observed. In the second, but always within two feet of the third stratum, have been found the teeth and bones of the hippopotamus, the teeth and bones of the elephant, the horns, bones and teeth of several species of deer, the horns, bones and teeth of the ox, and the shells of river-fish.

"The remains of hippopotami are so extremely abundant, that, in turning over an area of 120 yards in the present season, parts of six tusks have been found of this animal, besides a tooth and part of the horn of a deer, part of a tusk, and part of a grinder of an elephant, and the horns, with a small part of the skull, of an ox. One of these horns I had

an opportunity of measuring as it lay on the ground, and found it to be $4\frac{1}{2}$ feet in length, and five inches in diameter at the large end; it was found impracticable to remove it, otherwise than in fragments, which I have preserved, and have hopes of being able to put a considerable part of it together. The immense size of this horn is rendered more remarkable by another horn from the same spot, which measures but six inches in length. Though this stratum is so extremely productive of the remains of animals, yet there are but few good cabinet specimens from it, owing, it is presumed, to their having been crushed at the time they were buried, and to the injury they have since received from moisture. It is necessary to remark, that the gravel-stones in this stratum do not appear to have been rounded in the usual way by attrition, and that the bones must have been deposited after the flesh was off, because, in no instance, have two bones been found together which were joined in the living animal; and further, that the bones are not in the least worn, as must have been the case had they been exposed to the wash of a sea-beach.

"In the third stratum, *viz.* calcareous loam, have been found the horns, bones and teeth of the deer, the bones and teeth of the ox, together with snail-shells, and the shells of river-fish.

"Brentford, in the neighbourhood of which are the fields I have mentioned, is situated on the north bank of the Thames, and is six miles west of London.

"The fall of the Thames from Brentford to its mouth at the Nore, is estimated at seven feet."

The next communication is in relation to a fossil human skeleton, found imbedded in lime-stone lately brought from the island of Guadaloupe by the honourable sir Alexander Cochrane, and presented by the admiralty to the British Museum. Of this highly curious specimen Mr. Konig has given an account that, to naturalists, will be regarded as highly important and interesting.

"On the history of the strata produced by the more recent catastrophes of the globe," says Mr. Konig, "most light has been thrown by the indefatigable exertions of M. Cuvier. Superlatively skilled in comparative anatomy, this gentleman has succeeded in determining the fossil bones of no less than 78 species, of which 49 are entirely unknown among the existing races of animals; about 12 are identified with known species, and the remainder strongly resemble existing species, although their identity has not been completely ascertained. From the multiplied observations which this naturalist has communicated in his numerous memoirs, we may gather that the viviparous quadrupeds appear at a much later period in the fossil state than the oviparous; the latter being probably coeval with the fishes, whilst the former are found only in the newest formations, in which, according to Brongniart and Cuvier's interesting discovery, marine beds are observed to alternate with those of fresh water, and which (in the neighbourhood of Paris) overlay the coarse shell lime-stone, which constitutes the last strata formed, as it would appear, by a long and quiet stay of the sea on our continent.

"All the circumstances under which the known depositions of bones occur, both in alluvial beds and in the caverns and fissures of flint lime-stone, tend to prove, that the animals to which they belonged met their fate in the very places where they now lie buried. Hence, it may be considered as an axiom, that man, and other animals, whose bones are not found intermixed with them, did not co-exist in time and place. The same mode of reasoning would further justify us in the conclusion, that, if those catastrophes which overwhelmed a great proportion of the brute creation were general, as

geognostic observations in various parts of the world render probable, the creation of man must have been posterior to that of those genera and species of mammalia which perished by a general cataclysm, and whose bones are so thickly disseminated in the more recent formations of rocks.

"The human skeletons from Guadaloupe are called Galibi by the natives of that island; a name said to have been that of an ancient tribe of Caribs of Guiana, but which, according to a plausible conjecture, originated in the substitution of the letter *l* instead of *r*, in the word Caribbee. No mention is made of them by any author except general Ernouf, in a letter to M. Faujas St. Fond, inserted in vol. v. (1805) of the *Annales du Muséum*; and by M. Lavoisse, in his *Voyage à la Trinidad*, &c. published in 1813. The former of these gentlemen writes, that, on that part of the windward side of the Grande-Terre, called La Moule, skeletons are found enveloped in what he terms "Masse de madrepores pétrifiées," which being very hard, and situated within the line of high water, could not be worked without great difficulty, but that he expected to succeed in causing some of these masses to be detached, the measurements of which he states to be about eight feet by two and a half.

"The block brought home by sir Alexander Cochrane exactly answered this account with regard to the measurements; in thickness it was about a foot and a half. It weighed nearly two tons; its shape was irregular, approaching to a flattened oval, with here and there some concavities, the largest of which, as it afterwards appeared, occupying the place where the thigh-bone had been situated, the lower part of which was therefore wanting. Except the few holes evidently made to assist in raising the block, the masons here declared, that there was no mark of a tool upon any part of it; and, indeed, the whole had very much the appearance of a huge nodule disengaged from a surrounding mass.

"The situation of the skeleton in the block was so superficial, that its presence in the rock on the coast had probably been indicated by the projection of some of the more elevated parts of the left fore-arm.

"The skull is wanting; a circumstance which is the more to be regretted, as this characteristic part might possibly have thrown some light on the subject under consideration, or would, at least, have settled the question, whether the skeleton is that of a Carib, who used to give the frontal bone of the head a particular shape by compression; which had the effect of depressing the upper, and protruding the lower edge of the orbits, so as to make the direction of their opening nearly upwards, or horizontal, instead of vertical.

"The vertebrae of the neck were lost with the head. The bones of the thorax bear all the marks of considerable concussion, and are completely dislocated. The seven true ribs of the left side, though their heads are not in connection with the vertebrae, are complete; but only three of the false ribs are observable. On the right side only fragments of these bones are seen; but the upper part of the seven true ribs of this side are found on the left, and might at first sight be taken for the termination of the left ribs. The right ribs must, therefore, have been violently broken, and carried over to the left side, where, if this mode of viewing the subject be correct, the sternum must likewise lie concealed below the termination of the ribs. The small bone dependent above the upper ribs of the left side, appears to be the right clavicle. The right os humeri is lost; of the left nothing remains except the condyles in connection with the fore-arm, which is in the state of pronation; the radius of this side exists nearly in its full length, while of the ulna the lower part only remains, which is considerably pushed upwards. Of the two bones of the right fore-arm, the inferior termina-

tions are seen. Both the rows of the bones of the wrists are lost, but the whole metacarpus of the left hand is displayed, together with part of the bones of the fingers: the first joint of the fore-finger rests on the upper ridge of the os pubis, the two others, detached from their metacarpal bones, are propelled downwards, and situated at the inner side of the femur, and below the foramen magnum ischii of this side. Vestiges of three of the fingers of the right hand are likewise visible, considerably below the lower portion of the fore-arm, and close to the upper extremity of the femur. The vertebræ may be traced along the whole length of the column, but are in no part of it well defined. Of the os sacrum, the superior portion only is distinct: it is disunited from the last vertebra and the ilium, and driven upwards. The left os ilium is nearly complete; but shattered, and one of the fragments depressed below the level of the rest: the ossa pubis, though well defined, are gradually lost in the mass of the stone. On the right side the os innominatum is completely shattered, and the fragments are sunk; but towards the acetabulum, part of its internal cellular structure is discernible.

"The thigh-bones and the bones of the leg of the right side are in good preservation, but being considerably turned outwards, the fibula lies buried in the stone, and is not seen. The lower part of the femur of this side is indicated only by a bony outline, and appears to have been defended by the compact lime-stone that fills the cavities both of the bones of the leg and thigh, and to the expansion of which these bones probably owe their present shattered condition. The lower end of the left thigh-bone appears to have been broken and lost in the operation of detaching the block; the two bones of the leg, however, on this side are nearly complete: the tibia was split almost the whole of its length a little below the external edge, and the fissure being filled up with lime-stone, now presents itself as a dark-coloured straight line. The portion of the stone which contained part of the bones of the tarsus and metatarsus was unfortunately broken; but the separate fragments are preserved.

"The whole of the bones, when first laid bare, had a mouldering appearance, and the hard surrounding stone could not be detached, without frequently injuring their surface; but, after an exposure for some days to the air, they acquired a considerable degree of hardness. Sir H. Davy, who subjected a small portion of them to chemical analysis, found that they contained part of their animal matter, and all their phosphate of lime. Here follows an exact description of the rock, in which the fossil skeleton is found. The attention of geologists being now directed towards this object, it may be expected that a scientific examination of the circumstances under which this lime-stone occurs, will not fail ere long to fix its age, and assign to it the place it is to occupy in the series of rocks. All our present information respecting the Grande Terre of Guadeloupe amounts to this, that it is a flat lime-stone country, derived principally from the detritus of zoophytes, with here and there single hills (mornes) composed of shell lime-stone; while Guadeloupe, properly so called, separated from the upper part by a narrow channel of the sea, has no traces of lime-stone, and is entirely volcanic."

M. Lavoisier, alluded to above as the only author who mentions the galibies, except general Ernouf, speaks of the bed of lime-stone which incloses them, as the most remarkable of the calcareous rocks in the Leeward islands. Mr. König, therefore, expected to find in his work an exact statement of its mode of occurring; but the only positive information he could collect from this author is, that the bed is a kilomètre (nearly an English mile) in length, and

that it is covered by the sea at high water. According to him, no trace of shells or organized bodies is discoverable in this rock; but in lieu of these, he was fortunate enough to meet with mortars, pestles, hatchets, &c. of a basaltic or porphyritic rock, which, we are informed, were petrified (petrifiés). From this very vague account, we should not be induced to lay much stress upon the circumstance that the position of the skeletons is east-west, and that the spot must, therefore, have been a cemetery, which time and circumstances have transformed into a hard calcareous rock.

"I have to apologise for this long letter on a subject," concludes Mr. König, "which may turn out to be interesting only so far, as the human bones from Guadeloupe are unquestionably the only bones we are acquainted with that have ever been found imbedded in a hard stony mass, that does not appear to belong to common stalactitical calcareous depositions. This circumstance admits of being easily ascertained by a close inspection of the locality; and I am perfectly of opinion, that a comparison of the nature of the different varieties of shell-sand, with which the neighbourhood of the Caribbee islands abounds, would alone be sufficient to remove many doubts relative to the origin of the bed in question. The sand from thence, which I had an opportunity of seeing, was unlike that of which the stone is composed."

RELL, MOUSE, in *Zoology*, the English name of the white-bellied mouse, with a blackish back and long body. See MYOXUS and GLIS.

RELLING, in *Geography*, a town of the duchy of Holstein; 2 miles S.S.E. of Pinneberg.

RELLINGEN, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Thionville. The place contains 602, and the canton, 9046 inhabitants, on a territory of 212½ kilometres, in 36 communes.

RELLINGHAUSEN, a town of Germany, lately belonging to the abbey of Corvey; 16 miles N.N.E. of Duffeldorf.

RELLINGHUSEN, a town of the duchy of Holstein; 9 miles E. of Itzehoa.

REM, *Information in*, in *Law*. See INFORMATION.

RETAGEN, in *Geography*, a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Bonn. The place contains 790, and the canton 7801 inhabitants, in 37 communes.

REMAIGHIAN, a town of Persia, in the province of Laristan; 10 miles N.W. of Tarem.

REMAINDER, REMANENTIA, in *Law*, an estate limited to take effect and be enjoyed after another estate is determined. As if a man seized in fee-simple granteth lands to A for twenty years, and, after the determination of the said term, then to B and his heirs for ever: here A is tenant for years, remainder to B in fee. In the first place, an estate for years is created or carved out of the fee, and given to A; and the residue or remainder of it is given to B. But both these interests are in fact only one estate; the present term of years and the remainder afterwards, when added together, being equal only to one estate in fee. (Co. Litt. 143.) Thus, also, if land be granted to A for twenty years, and after the determination of the said term to B for life; and after the determination of B's estate for life, it being limited to C and his heirs for ever: this makes A tenant for years, with remainder to B for life, remainder over to C in fee. In this case also, the first estate, and both the remainders, for life and in fee, are one estate only. Hence it is easy to infer, that no remainder can be limited after the grant of an estate in fee-simple (Plover. 29.

Vaugh. 269.) ; because this is the highest and largest estate that a subject is capable of enjoying ; and he that is tenant in fee, hath in him the whole of the estate : a remainder, therefore, which is only a portion, or residuary part of the estate, cannot be reserved after the whole is disposed of.

The rules that are laid down by law to be observed in the creation of remainders, are as follow. 1. There must necessarily be some particular estate, precedent to the estate in remainder ; which particular estate is said to support the remainder. (Co. Litt. 49. Plowd. 25.) 2. The remainder must commence or pass out of the grantor, at the time of the creation of the particular estate (Litt. § 671. Plowd. 25.) : as where there is an estate to A for life, with remainder to B in fee ; here B's remainder in fee passes from the grantor at the same time that seisin is delivered to A of his life-estate in possession. And it is this which induces the necessity at common law of livery of seisin being made on the particular estate, whenever a freehold remainder is created. (Litt. § 60. Co. Litt. 49.) 3. The remainder must vest in the grantee during the continuance of the particular estate, or *eo instanti* that it determines. (Plowd. 25. 1 Rep. 66.) As if A be tenant for life, remainder to B in tail : here B's remainder is vested in him, at the creation of the particular estate to A for life : or if A and B be tenants for their joint lives, remainder to the survivor in fee ; here, though during their joint lives the remainder is vested in neither, yet on the death of either of them, the remainder vests instantly in the survivor ; whence both these are good remainders. But if an estate be limited to A for life, remainder to the eldest son of B in tail, and A dies before B hath any son ; here the remainder will be void, for it did not vest in any one during the continuance, nor at the determination, of the particular estate : and even supposing that B should afterwards have a son, he shall not take by this remainder ; for, as it did not vest at or before the end of the particular estate, it never can vest at all, but is gone for ever. (1 Rep. 138.) Hence remainders are either *vested* or *contingent*. *Vested* remainders (or remainders executed, by which a present interest passes to the party, though to be enjoyed in *future*) are such where the estate is invariably fixed, to remain to a determinate person after the particular estate is spent. As if A be tenant for twenty years, remainder to B in fee ; here B's is a *vested* remainder, which nothing can defeat or set aside. *Contingent* or executory remainders (by which no present interest passes) are where the estate in remainder is limited to take effect, either to a dubious and uncertain person, or upon a dubious or uncertain event ; so that the particular estate may chance to be determined, and the remainder never take effect. (3 Rep. 20.) In the first case, if A be tenant for life, with remainder to B's eldest son (then unborn) in tail, this is a contingent remainder, because it is uncertain whether B will have a son or not ; and if A dies before B's son is born, the remainder is absolutely gone ; even though A leaves his wife big with child, and after his death a posthumous son is born. (Salk. 228. 4 Mod. 282.) But to remedy this hardship, it is enacted by statute 10 & 11 W. III. cap. 16. that posthumous children shall be capable of taking in remainder, in the same manner as if they had been born in their father's life-time ; that is, the remainder is allowed to vest in them, while yet in their mother's womb. This species of contingent remainder, to a person not in being, must, however, be limited to some one, that may by common possibility, or *potentia propinqua*, be in *esse* at or before the particular estate determines. (2 Rep. 51.) A remainder to a man's eldest son, who has none, is good ; because by common possibility he may have one : but if it be

limited in particular to his son John or Richard, it is bad, if he have no son of that name ; for it is too remote a possibility, that he should not only have a son, but the son of a particular name. (5 Rep. 51.) A limitation of a remainder to a bastard before he is born, is not good (Cro. Eliz. 505.) ; for though the law allows the possibility of having bastards, it presumes it to be a very remote and improbable contingency. In the second case, where land is given to A for life, and in case B survives him, then with remainder to B in fee : here B is a certain person, but the remainder to him is a contingent remainder, depending upon the uncertainty of his surviving A. During the joint lives of B and A, it is contingent ; and if B dies first, it can never vest in his heirs, but is for ever gone ; but if A dies first, the remainder to B becomes vested. Contingent remainders of either kind, if they amount to a freehold, cannot be limited on an estate for years, or any other particular estate, less than a freehold. Thus, if land be granted to A for ten years, with remainder in fee to the right heirs of B, this remainder is void (1 Rep. 130.) ; but if granted to A for life, with a like remainder, it is good. Contingent remainders may be defeated, by destroying or determining the particular estate upon which they depend, before the contingency happens, by which they become vested. 1 Rep. 66. 155.

In devises by last will and testament, remainders may be created in some measure contrary to the rules here laid down : though our lawyers will not allow such dispositions to be strictly remainders ; but call them by another name, that of executory devises, or devises hereafter to be executed. Blackst. Com. book ii. chap. 11. § 3.

Spelman makes the difference between a remainder and reversion to consist in this ; that by a reversion, after the appointed term, the estate returns to the donor, or his heirs, as the proper fountain ; whereas by remainder it goes to some third person or stranger.

Or, a remainder is an expectancy, created by act of the parties ; whereas a reversion is created by act of law.

The limitations of personal goods and chattels, in remainder after a bequest for life, are permitted in last wills and testaments : so that if a man, either by deed or will, limits his books or furniture to A for life, with remainder over to B, this remainder is good. But where an estate-tail in things personal is given to the first or any subsequent possessor, it vests in him the total property, and no remainder over shall be permitted on such a limitation. 1 P. Wms. 290.

Glanville observes, that bishops and abbots, in regard their baronies are the king's alms, cannot give any part of them by way of remainder.

REMAINDER, *Writ of formedon in the*. See FORMEDON.

REMAINDER, in *Mathematics*, is the difference ; or that which is left after the taking a lesser number, or quantity, from a greater.

REMAL, in *Geography*, a town of Hindooistan ; 18 miles N.W. of Agimere.

REMLAND, a town of France, in the department of the Orne, and chief place of a canton, in the district of Mortagne. The place contains 1702, and the canton 11,685 inhabitants, on a territory of 202½ kilometres, in 12 communes.

REMANCIPATE, *To*, in *Commerce*, is to sell or return a commodity to him who first sold it.

REMANCIPATION, REMANCIPATIO, among the Romans, a form of divorce observed in marriages that had been contracted by *coemptio*. This was done by delivering the wife into the husband's hands ; so the marriage was dissolved

solved by the husband's re-delivering the wife into any person's hands agreed upon between them.

REMAND, Fr., *To*, in *Military Language*, to send back; as when a soldier, who has been brought out of prison, or the guard-house, for the purpose of being examined or tried, is sent back, without any thing final occurring relative to his case.

REMANSO, in *Geography*, a town of South America, in the province of Cordova; 170 miles N. of Cordova.

RE-MARRYING, the repeating of a marriage; or the going through the solemnities of a second marriage.

Clandestine and uncanonical marriages are deemed null; and the parties are to be re-married in form; at least, it had always better be so to avoid disputes.

It was anciently expressly forbid to re-marry in the first year of viduity. M. Bayle observes, that a person who does not re-marry, is answerable to the public for all the time lost in his viduity, or widowhood.

REMBANG, in *Geography*, a town on the N. coast of the island of Java, where the Dutch had a resident merchant. It yields salt and timber, and was the place where the small vessels of the company were built; 45 miles N.E. of Samarang.

REMBERTUS, in *Biography*, the disciple, friend, and fellow labourer of Ansgarius, styled the apostle of the north, was a native of Thurholt, in Flanders, in the monastery of which, as well as in that of Corbey in Westphalia, he officiated as school-master. He was one of the first promoters of Christianity in Denmark, and in or about the year 860 he became bishop of Ribe. After the death of Ansgarius, in 865, he was appointed to the archbishopric of Hamburg, which office he held till his death, in 888. He wrote, in conjunction with a friend, the life of Ansgarius, which is inserted in the first volume of Langebeck's "Scriptores Rerum Danicarum." In this work Rembertus relates various facts, not elsewhere to be found, with regard to the state of Denmark at that period, but intermixed with fables. He collected extracts from Gregorius Magnus, whose works no longer exist, and he wrote many letters, one of which only is to be found in the second volume of Langebeck's collection. An account of Rembert's life and miracles is given in the same work. A Danish writer, quoted in the General Biography, to which we are indebted for this article, in speaking of Rembert's labours, says; "here we have not so much the commencement of Danish literature, as the seeds of it. They were sown by the exertions of Ebbo, Willehad, Ansgarius, and Rembert, but remained a long time, as it were, trodden down by the severe persecutions to which the Christians were exposed from Gormo the old, and other kings; and retarded in their growth by the rudeness and barbarism which formed the principal features in the character of a people, who were fond of roving about on the seas to rob and murder, and of feasting and drinking, than of reading and writing books. At length, however, the seeds which he had scattered took root, sprung up in the 11th century, and in the 12th and 13th produced abundance of fruit." Gen. Bog.

REMBERVILLERS, in *Geography*. See RAMBERVILLERS.

REMBRANDT, VAN RYN, in *Biography*, was born at a village near Leyden, in 1607. The real name of his family was Gerretsz.; but he acquired that of Van Ryn, from having resided in early life at a village upon the banks of the Rhine.

The little which this extraordinary artist owed to tuition was derived first from Zwanenburg, then from Peter Lastman, and afterwards from Jacob Pinas, from whose manner

some are induced to think that Rembrandt drew his own inclination for powerful oppositions of light and shade; but whatever hints he may have obtained from others at the outset of his practice, they were soon lost in the effulgence of his brilliant career, and absorbed in the lustre of his own over-powering abilities.

He was first brought into notice by having taken a picture to the Hague, and offered it for sale to an able connoisseur; who, conscious of his merit, treated him with kindness, and gave him a hundred florins for it. By this incident both himself and the public were made acquainted with his worth; and hence arose the reputation and success he afterwards enjoyed. Incessant occupation soon crowded upon him, and many pupils applied for admission into his school, with each of whom he received 100 florins a-year; and whose copies of his pictures he not unfrequently sold as originals, after bestowing a short time upon them himself. By these means, aided by incessant industry, and the sale of etchings, which he produced with great facility and skill, he accumulated considerable wealth: his income, according to Sandrart, being, for a length of time, at least 2500 florins yearly.

His place of residence, during this successful display of his talents, was Amsterdam, where his peculiarities procured him the character of a humorist, whilst his abilities astonished and delighted his contemporaries, and he produced those works which still gratify succeeding ages.

The peculiarities of his mind are as much observable in the manner of producing his effects, as in the choice of the materials. The execution of his earlier works was in a style highly laboured, with great neatness, and patient completion of the figures; such is that of the picture of the woman taken in adultery at Mr. Angerlein's. As he advanced in art, he took liberties with the pencil, wrought with all the broad fulness of the brush, and left the touch undisturbed: he even employed the stick, the pallet-knife, or his fingers, accordingly as they were most capable of producing the effect he desired, when seen at a proper distance, disregarding the appearance of the work upon a closer inspection.

In his pictures is exhibited a total inattention to the taste of the antique; he is even said to have made it a subject of ridicule, and to have jocosely denominated a collection of old armour and rich dresses, which he had collected and employed to study and paint from, "his antiques." These he evidently used as his models, though frequently in most heterogeneous combination; but by an innate power of seizing the most striking effects produced by light and shade, super-added to the most perfect mastery over the materials of the pallet, he always excited an interest, either by originality or beauty.

It is not, however, the approval of his power in the technical part of the art, which can or ought to satisfy the observer of the works of Rembrandt. Entering with the warmth of a poet into the nature of his subjects, he produced pictures which terrify with their sublimity, delight with their severity, or gratify us with the most perfect transcripts of Nature, in her most varied aspects. Being himself possessed of the full force of his subject, he impresses it strongly, and notwithstanding the frequent vulgarity, and even deformity of the agents he exhibits, he extorts from us praise before we have time to consider the means by which we are stimulated to bestow it. To him every time and season was alike easy of representation; and all degrees of illumination, in form or quantity, he managed with the greatest perfection; no matter whether the scene arose from the breadth of the noon-day blaze, the dimness of twilight,

the

the darkness of night, or the glimmerings of the lonely taper; whether the light were spread over an extended space and a multitude of figures, or confined to the interior of a room, and serving only to illumine the books or the figure of a sequestered philosopher.

He was certainly a genius of the first class, although the objects upon which he exercised his powers bore little or no proportional value when compared with those selected by the best Greek and Italian masters. His invention was abundantly fertile, but employed generally among low characters and materials, although the subject he treated might be, as it frequently was, of a sacred or sublime quality. In designing the nude, he never appears to have had a thought of an elevated nature concerning form. Such as the model presented, he imitated with exactness, when he wished to be most perfect; but he sometimes seems to have sported with the idea of selection, by making figures demanding grace and beauty, such as Venus, Cupid, &c. still more vulgar, and in actions more disgusting, than those he drew of common life. The redemption of this vulgarity and meanness rests with the extreme force, depth, richness, brilliancy, and truth of his colouring, and the perfection with which he treated his chiaro-scuro; which conjointly fascinate the eye, and hold it in admiration, in spite of the deformities presented in design.

The power of Rembrandt in the art he practised was perfectly original, and its exercise quite unlike that of any other painter; being drawn from nature with the most faithful and discriminating eye, but with the most peculiar selection. Always powerfully and beautifully executed, but not unfrequently too artificial; and only agreeable because it is perfectly effective. All imitations of his style which are not well wrought, reduce it to manner, and only exhibit the artifice by which it is conducted.

To guess from the number and finish of his works, he must have painted with amazing facility. His system appears to have been that of using the ground as a half teint, and repeating the lights and darks till he had obtained the effect he sought for. His pencil, particularly in his earlier and more finished works, is remarkably delicate, yet full; and has never been exactly imitated; though some of his scholars, as Bohl and Eckhout, approached very near it: none of them, however, appear to have imbibed any large portion of his clear perception of natural effects, which so powerfully appeals to our sympathy in his scenes of twilight, of tempest, and the spirit-stirring gloom of night.

His pictures are jolly and highly valued, and are rarely to be purchased; and then only at very high prices. We are possessed of many fine specimens of his talents, both in history and portraiture; and the gallery of the Louvre is rich in his smaller productions. At Florence also, and at Genoa, his name is esteemed, and his works preserved with due respect.

He lived to the age of sixty-eight, and died in 1674.

REMDA, in *Geography*, a town of Saxony, in the principality of Eisenach; 11 miles S.S.W. of Jena. N. lat. 50°45'. E. long. 11°19'.

REMEDIAL *Part of a Law*. See LAW.

REMEDIAL *Statutes*, are those which are made to supply such defects, and abridge such superfluities, in the common law, as arise either from the general imperfection of all human laws, from change of time and circumstances, from the mistakes and unadvised determinations of unlearned judges, or from any other causes whatsoever. And this being done, either by enlarging the common law where it was too narrow and circumscribed, or by restraining it where it was too lax and luxuriant, hath occasioned another subordinate division

of remedial acts of parliament into enlarging and restraining statutes. *E. gr.* In the case of treason, clipping the current coin of the kingdom was an offence not sufficiently guarded against by the common law; therefore it was thought expedient by statute 5 Eliz. cap. 11. to make it high treason, which it was not at the common law; so that this was an enlarging statute. At common law also spiritual corporations might lease out their estates for any term of years, till prevented by the statute 13 Eliz. cap. 10. This was, therefore, a restraining statute. Blackst. Com. book i.

REMEDIOS, in *Geography*, a town of South America, in the province of Popayan; 71 miles S. of Santa Fé de Antioquia.

REMEDIOS, or *Nostra Señora de los Remedios de Pueblo Nuevo*, a town of Mexico, in the province of Veragua; 90 miles W.N.W. of St. Yago. N. lat. 8°44'. W. long. 82°16'.

REMEDIOS, or *Payasal*, a town of Mexico, in the province of Yucatan, in lake Pue. N. lat. 17°3'. W. long. 91°46'.

REMEDIOS, a town of New Navarre; 120 miles S. of Casa Grande.

REMEDY, in *Law*, is the action or means given by law for the recovery of a right.

REMEDY, *Remedium*, in *Medicine*, any physical agent by which a disease may be alleviated or cured.

Remedies are either *general* or *topical*; the former comprehending such as influence the actions of the whole frame, as blood-letting from any large vein, the cold-bath, and almost all those medicaments or drugs which are taken into the stomach; the latter including those which are applied to, or in the vicinity of, any particular part which is diseased: thus, among *topical* remedies, are blood-letting by leeches or cupping, blisters, issues, cataplasms, ointments, plasters, &c.

The operation of remedies is rather a question of experience than of logical investigation. Some remedies, the number of which appears to be very limited, possess a *specific* power of curing certain diseases. There are, perhaps, not more than two medicines, however, that are fairly entitled to the appellation of *specifics*: these are mercury, which cures the venereal disease, and sulphur, which cures the itch. The bark of cinchona has, indeed, been deemed a specific for intermittent fevers; but it is not entitled to such a character: and the cau medicinale, which has recently been brought forward as a specific for the gout, appears to have lost much of its reputation. The pretended specifics daily advertised for many diseases by quacks, are mere impositions, being commonly disguised forms of the most active and dangerous medicines which are employed cautiously by the faculty; such as arsenic, corrosive sublimate, and other preparations of mercury; laudanum, hemlock, and other narcotics. Of the former species are Ward's ague-drop, and his white drop; of the latter, are Dalby's carminative, Godbold's balsam, and many others. The danger resulting from the use of these nostrums, arises from the indiscriminate administration of them in many diseases which have a similar name, but which vary much in different constitutions, and at different periods of life. Much injury is done by the constant sale of these pretended specifics, by the impression which it contributes to maintain, that each disease has its specific remedy; whereas no opinion can be farther from the truth. When it is considered that almost every disease, though similar in name, arises from several causes (which we have already illustrated when speaking of COUGH), it will be obvious that the same remedies must be applied, upon general principles, to diseases of different name, and different remedies to those which have the

same appellation; and that, therefore, the cure of diseases is not to be effected by applying a certain remedy to a certain disease nominally the same, but only by first ascertaining the laws of the living body, and of its various organs, both in a state of health and of disease: in other words, the proper application of remedies can only be learned by much observation of diseases, after a previous study of the anatomy and physiology of the animal frame.

REMEDIES *Appended.* See APPENSA.

REMEDY *for the Master of the Mint, in Coinage,* denotes a certain allowance for deviation from the standard weight and fineness of coins. In some places the remedy is allowed in the weight, in others in the fineness; but mostly in both weight and fineness. It is considered generally as an allowance for the fallibility of workmanship; but in some foreign mints it is made a source of emolument: and when governments issue coins at a rate above their intrinsic value, the profit thus made is called "seignorage." Out of every fifteen pounds of gold coined at the mint in London (according to the account published by the learned Mr. Folkes, in his curious tables of English silver coins), some pieces are taken at random, and deposited in a strong box, called the *pix*: at certain intervals, sometimes of one year and sometimes of several years, the *pix* is opened at Westminster, in the presence of the lord chancellor, the lords commissioners of the treasury, and others; portions taken from the pieces of each coinage are melted together, and an assay made of the collective mass by a jury of the goldsmiths' company. At this trial the mint-master is held excusable, though the monies be either too base, or too light; provided the imperfection and deficiency together are less than the sixth part of a carat, which amounts to forty grains of fine gold on the pound of standard, or the one hundred and thirty-second part of the value. It is said that this remedy is contained within as narrow limits, as any workers can reasonably be supposed to make themselves answerable for. The remedy for silver coins is two pennyweights in the pound. If the deficiency or excess of the coin should be more than this, either in the weight, or in the fineness, or in both together, the money must be recoined at the expence of the master of the mint; and no allowance is made for remedy unless the error is supposed to have casually happened.

REMEE, in *Geography*, a town of Bengal; 16 miles S. of Koonda.

REMEMBRANCE, is when the idea of something formerly known recurs again to the mind, without the operation of a like object on the external sensory. See MEMORY, REMINISCENCE, and RECOLLECTION.

REMEMBRANCERS *of the Exchequer*, are two officers, or clerks, therein, formerly called *clerks of the remembrance*.

They are now distinguished by the appellations of the *king's remembrancer*, and the *lord treasurer's remembrancer*. There is also another officer, called the *remembrancer of first-fruits*. Their business is to put the lord treasurer and justices of the court in remembrance of such things as are to be called upon, and dealt in for the king's benefit.

REMEMBRANCER, *The King's*, enters into his office all recognizances taken there before the barons, for any of the king's debts; for appearance; or for observing orders; and makes out process against the collectors of customs, subsidies, excise, and other public payments, for their accounts. All informations upon penal statutes are entered in this office; and there all matters upon English bills in the exchequer chamber remain. He makes the bills of composition upon penal laws; takes the statement of debts; has

delivered into his office all manner of indentures, fines, and other evidences whatsoever that concern the assuring of any lands to the crown: he every year, in *crastino Animarum*, reads, in open court, the statute for election of sheriffs, and gives them their oath, and reads the oath of all the officers of the exchequer, where they are admitted.

REMEMBRANCER, *The Lord Treasurer's*, is charged to make process against all sheriffs, escheators, receivers, and bailiffs, for their account; process of fieri facias, extent for any debts due to the king, either in the pipe, or with the auditors; and process for all such revenues as are due to the king, by reason of his tenures. He also makes record, by which it appears, whether sheriffs, or other accountants, pay their proffers due at Easter and Michaelmas. He makes another record, whether sheriffs, or other accountants, keep their days of prefoxion: all estreats or fines, issues, and amerciements, set in any of the courts of Westminster, or at the assizes or sessions, are certified into his office, and are by him delivered to the clerk of the estreats to write process upon them, &c.

REMEMBRANCER *of the First Fruits*, he who takes all compositions and bonds for first fruits and tenths; and makes process against such as do not pay the same.

REMEMBRANCER is also the title of an officer in the city of London, who is to attend the lord mayor on certain days, and whose business is to remind his lordship of the select days, when he is to go abroad with the aldermen, &c. He is to attend daily at the parliament-house during the sessions, and to report to the lord mayor their transactions.

REMI, St., in *Biography*, archbishop of Rheims, who converted Clovis to Christianity, and baptized that monarch. He died about the year 535. There are some letters which pass under his name, but they are of a very doubtful authority. There was another saint of this name, or, as he is sometimes styled, REMIGIUS, who was archbishop of Lyons, and presided in the council of Valentia in 855. He was a steady supporter of the doctrine of St. Augustine, on grace and predestination, in several works that are now extant. He died in 875.

REMI, JOSEPH HONORE, an advocate in the parliament of Paris, was born in 1738. At the age of eight he lost his sight, and it was believed irrecoverably, by the small-pox; but when he had attained the age of fourteen he was in the enjoyment of his eyes. He was author of a burlesque poem, entitled "Days," in opposition to Young's Night Thoughts; but his principal work is an eloge on the chancellor de L'Hôpital, which was crowned by the French academy in 1777, and censured by the Sorbonne. He also wrote the eloges of Moliere, Colbert, and Fenelon, and furnished the articles relating to jurisprudence for the French Encyclopædia. He died in the year 1782.

REMI of Auxerre. See REMIGIUS.

REMI, *Order of St.*, or of the *Holy Vial*, an order of knighthood in France, which, according to the most approved historians of that kingdom, was instituted by Clovis, king of France, in the year 499. The reigning king of France is always sovereign of this order, and the knights companions are never more than four; nor is it ever conferred on any persons but the barons, Terrier, Belestre, Venestre, and Louverse, who stile themselves baron knights of the Holy Vial, and are the bearers of the canopy under which the vial is carried from the abbey of St. Remi to the cathedral of Rheims, for the inauguration of the kings of France at their coronations. The badge of this order, which is worn pendant to a black ribbon, is "a cross of gold, enamelled white, cantoned with four fleur-de-lis; on the
crosses,

cross, a dove descending, dipping its beak into a vial held in a hand, all proper."

REMICH, in *Geography*, a town of France, in the department of the Forests, and chief place of a canton, in the district of Luxembourg, seated on the Moselle; 12 miles E. of Luxembourg. The place contains 1480, and the canton 10,885 inhabitants, on a territory of 230 kilometres, in 15 communes.

REMIGES, in *Ornithology*, denote the primary and secondary wing-feathers.

REMIGIO, FIORENTINO, in *Biography*, a man of letters in Italy, was a native of Florence. He entered at an early period into the Dominican order, and was called to Rome by pope Pius V. to superintend an edition of the works of St. Thomas. He was himself a considerable author, and published "A Commentary on the whole Scriptures;" translations of "Ammianus Marcellinus;" "Cornelius Nepos;" and "Fazello's History of Sicily;" "Reflections on Guicciardini's History;" "Italian Poems;" and "A Translation in Verse of Ovid's Heroic Epistles," of which an elegant edition was printed at Paris in 1762. He died at Florence in 1580, about the age of 62. Moreri.

REMIGIUS. See REMI.

REMIGIUS of Auxerre, a learned French Benedictine monk in the ninth century, derived his surname from the abbey of St. Germain, at Auxerre, where he embraced the religious profession. He distinguished himself by his proficiency in profane and sacred literature, at a dark and barbarous period, and was placed at the head of the schools belonging to his monastery. About the year 882, he was called to Rheims by Foulques, the successor of Hincmar in that see, who gave him the direction of the literary seminary which he had founded in his metropolitan city. Here he taught with great reputation for several years, after which he went to Paris, where he opened the first public school in that city, after the decline of learning which followed the ravages of the Normans. In the life of pope Formosus, by Platina, the name of Remigius of Auxerre is the only one that occurs of a person eminent for learning under that pontificate. He was author of "Commentarius in omnes Davidis Psalmos," which was published at Cologne in 1536. It consists very much of the collected opinions and explications of St. Ambrose, St. Augustine, and Cassiodorus, reduced into one mass.—Another work of this author was entitled "Enarratio in posteriores XI. minores Prophetas," published at Antwerp in the year 1545, with the "Commentaries" of Oecumenius upon the Acts of the Apostles, and their Epistles, and those of Arethas upon the book of Revelation; and "Expositio Missæ," deduced from the sentiments and authority of the fathers. Some critics have given, among the productions of Remigius, the "Commentary upon the Epistles of St. Paul," which by others has been ascribed to St. Remi, or Remigius, but which in truth are supposed to belong to Haymo, a German bishop, who flourished in the ninth century, and who was author of a long list of theological works. Such at least is the opinion of Du Pin, in opposition, indeed, to the authority of Mosheim. Moreri.

Remigius left behind him "A Commentary on the Musical Treatise of Martianus Capella," which is still subsisting among the MSS. in the king of France's library, N° 5304. He acquired his science from Heric. Heric was the disciple of Rabanus, and Hayman of Halberstadt, who had conversed with the Roman singers sent into France by pope Adrian.

REMILLY, in *Geography*, a town of France, in the department of the Ardennes; 7 miles W. of Charleville.

REMINISCENCE, REMINISCENTIA, is that power of the human mind, by which it recollects itself, or calls again to its remembrance such ideas or notions as it had really forgot: in which it differs from *memory*, which is a treasuring up of things in the mind, and keeping them there, without forgetting them.

Hence memory may be considered as a continual remembrance; and reminiscence as an interrupted memory.

How near akin soever the two faculties may seem, yet they are generally found separated; so that they who excel in the one, are generally defective in the other.

The ancient Platonists were of opinion, that all learning and knowledge consisted in the reminiscence or recollection of notices which had been in the soul before its union with the body.

REMINISCERE, the second Sunday in Lent; anciently thus called from the first word of the introit of the mass said for that day, "Reminiscere miserationum tuarum."

REMIREA, in *Botany*, Aubl. Guian. 44. t. 16. Brown Prodr. Nov. Holl. v. 1. 236. (See MIEGIA.) We are unacquainted with Mr. Brown's reasons for preferring the above name, whose origin does not appear, and which the classical Schreber rejected as barbarous.

REMIREMONT, in *Geography*, a town of France, and principal place of a district, in the department of the Vosges; 10 miles S.S.E. of Epinal. The town contains 3250, and the canton 14,916 inhabitants, on a territory of 235 kilometres, in 15 communes. N. lat. 48° 1'. E. long. 6° 40'.

REMISIT. — *Recto quando dominus Remisit.* See RECTO.

REMISSAM, in *Geography*. See REMSA.

REMISSION, in *Law*, &c. denotes the pardon of a crime, or the giving up the punishment due to it.

REMISSION, in *Medicine*, is when a distemper abates, but does not go quite off, before it returns again: as is common in fevers which do not quite intermit. See REMITTENT.

REMISSION, *Remissio*, in *Physics*, the abatement of the power or efficacy of any quality. In opposition to the increase of the same, which is called its *intension*.

In all qualities capable of intension and remission, the intension decreases as the squares of the distance from the centre of the radiating quality increase.

REMISSION, *Remissio*, *απεισις*, in the *Ancient Music*, was used to signify the passage of the voice from acute to grave, being opposite to intension.

REMIT, in *Commerce*. To remit a sum of money, bill, or the like, is to send a sum of money, &c.

To remit is also used among bankers for what is accustomed to be given a banker, or, as it were, discounted with him, for his giving a bill of exchange.

To remit is also to give up part of one's due to a debtor; as, I would remit you a fourth of what you owe on condition of paying me the rest in hand.

REMITTANCE, in *Commerce*, the traffic or return of money from one place to another, by bills of exchange, orders, or the like.

A remittance is properly a bill of exchange, or the like, sent to a correspondent, and the content of it to be received by him, or some other person, on whom it is drawn. By means of these remittances, large sums of money are returned from one city to another, without danger, without carriage, &c.

In London it is easy to get remittances upon any city in the world; in the country it is more difficult.

REMITTANCES, *Book of*. See BOOK.

REMITTANCE is also used in speaking of the payment of a bill of exchange.

REMITTANCE also denotes the due or fee allowed the banker or merchant, both on account of his trouble, and the different value of the species in the place where you pay the money, and where he remits it.

This remittance is more usually called *change* and *rechange*.

REMITTENT, in *Medicine*, implying also the word *fever*, is a fever which is characterized by a regular decrease and exacerbation of its symptoms every day, and differs from an *intermittent*, inasmuch as the symptoms never disappear altogether, and the exacerbation is neither begun by the complete rigors, nor terminated by the profuse sweat, which occur in the latter. The remittent fever, however, originates, in common with the intermittent, from the influence of marsh effluvia, but under particular circumstances, which will be stated immediately.

It is scarcely necessary to describe minutely the symptoms of the remittent fever after the ample detail which we have given of those of fever in general (see FEVER); and it varies extremely in its character, according to the season, climate, and other circumstances under which it appears. In its milder forms, the remittent begins with chilliness, lassitude, pains in the bones, head-ache, and a disordered condition of the stomach, loss of appetite, sickness, and even vomiting. At night the febrile symptoms run high; the heat and thirst are great, the tongue and mouth are parched, the pain of the head is violent, the patient is totally unable to sleep, and is continually tossing and tumbling about, and often becomes delirious. But generally in the morning, an imperfect sweat brings on a remission of all the symptoms. In the evening, the paroxysm returns, but is not preceded by any cold fit or shivering; yet it is commonly more severe than the former. Next morning it remits as before; and these periodical changes recur daily, becoming, however, less marked, if the disease be neglected, until the fever insensibly assumes a continued form. The pulse is full and quick during the exacerbations, and continues during the remissions to indicate fever; but rigors seldom precede the fits after the first attack. Many patients discharge a bilious matter from their stomachs by vomiting, and all are disordered in that organ. In the more violent forms, which take place in hotter seasons and climates, the disease often seizes the patient at once with a burning and violent head-ache, with little or no sensible chilliness preceding it. The thirst and heat are intense, and acute pains in the back and all the limbs, with extreme lassitude and inquietude, harass the patient, and nausea, vomiting, and pain of the stomach ensue. In some instances, indeed, the head becomes so suddenly and violently affected, that a violent delirium, assuming the appearance of insanity, seizes the patient without any previous indication, until the remission evinces the nature of the disease. Many of the sick become yellow, as if affected with jaundice. Indeed, the remittent fever assumes every degree of violence, from the autumnal bilious fever of temperate climates, to the most severe *yellow fever* of tropical countries.

The circumstances under which these varieties of form occur, have been amply ascertained by experience. The combination of marsh effluvia and great heat are necessary to the production of these fevers; and they are violent, nearly in proportion to the degree of the latter. In cold climates, and in cool seasons, as the spring, the miasmata excite but the common intermittent ague. But in the au-

tumnal season; especially when the heat is considerable, and the quantity of miasma great, as in the Low Countries, in particular years, the production of these fevers is very extensive; they become actually endemic, and affect especially those persons who are not accustom'd to the climate. The experience of all our military expeditions to Holland and Flanders, in the autumnal season, affords fatal proof of this truth. (See the writings of sir John Pringle, Dr. Home, &c. on the Diseases of the Army in the Campaigns of 1742—1748, inclusive. And the severe epidemic of Walcheren, at a more recent period, cannot be forgotten.) In these climates, the *remittent* usually commences at the close of summer, in a milder form, and gradually assumes a more violent and formidable character, as the heats of autumn advance. But if we extend our inquiries to the hotter regions of the globe, we find the disease under its most severe and fatal forms. In the south of Europe, especially in Spain, and those parts of the Mediterranean coasts where miasmata are found, the autumnal remittent becomes a formidable malady in particular seasons; but we must proceed to the West Indies and America to discover the disease in its most terrific form; for although there may be a contagious fever, which puts on the *yellow* or bilious character, Dr. Bancroft appears to have demonstrated, satisfactorily, that the *yellow fever*, commonly so called, is but the severest form of the endemic remittent of the hot seasons of hot climates. (See his able "Essay on the Disease called Yellow Fever, &c." 1811). He affirms, indeed, that all fevers, occurring in those countries in which the atmospheric heat rises, during certain seasons, to the 85th degree of Fahrenheit's thermometer, have a tendency to assume that violent and dangerous appearance, which is usually considered as characteristic of the yellow fever.

The testimony of all experienced medical observers concurs in proving the origin of remittent fevers from the influence of miasmata. Thus, among the historians of disease, as it occurs among seamen in warm climates, Drs. Lind, Blane, Hunter, and others, have demonstrated the exclusive attacks of these fevers to be among those men who have gone on shore, in swampy grounds, for water, &c.; and especially among those who spend the night on shore. Many instances are recorded, in which all the men so employed have been seized with fevers, while the rest of the ship's company have remained in health. (See Dr. Lind, on the Diseases incidental to Europeans in Hot Climates, p. 27. 221, &c. 5th edit. Dr. Blane, on the Diseases of Seamen, p. 92, and 392.) Again, sir John Pringle, in his valuable work on the diseases of the army, has not only stated many facts which occurred under his own observation, but has adduced many proofs from the writings of ancient physicians and historians, in corroboration of the evidence that these fevers have, every where, and at all times, originated in hot seasons, in circumstances where miasmata existed. (Part 3. chap. iv. sect. 3.) In times, indeed, not very remote, when the want of proper means of carrying off the filth and refuse of large towns by proper drains, and scavengers were not employed, and when the materials for the production of miasmata were accumulated even in the streets, the remittent and intermittent fevers were epidemic, in favourable seasons, for the generation of the miasmata, and the source of considerable fatality. Thus, even in London, Dr. Short remarks that, early in the seventeenth century, "one of forty of the whole that died of fevers, died of agues." (See his New Observations, &c. on Bills of Mortality, p. 203.) And Burnet, in his History of the Reformation, says, that in the last year of queen Mary's reign, they "rag'd like a plague." At a later period, we have

REMITTENT.

have the testimony of Sydenham and Morton, in proof of the great prevalence of remittents in London; and Morton affirms that they were extremely destructive for several years before the great plague, viz. from 1658 to 1664. He states that Oliver Cromwell died of an attack of remittent fever in the former of these years, and that he lost his own father, who was himself an experienced physician, from the same disease, which had gone through his whole family. (Morton, *Pyretologia*, append. ad Exerc. ii.) "The result of the whole, therefore, is," to use the words of Sir John Pringle, "wherever the greatest causes of moisture and putrefaction in the air exist, there also will be seen the greatest number and the worst kinds of the remitting and intermitting fevers." This truth is farther confirmed by the negative evidence, that these fevers have ceased to exist where marshes have been drained, where towns have become cleanly, when armies have moved to dry situations, and when the heats of particular seasons have ceased, or failed to occur.

What the nature of these miasmata is, the investigations of philosophers have not yet taught us. Dr. Bancroft has entered at great length, and with great ability, into this question, reasoning from a large collection of important evidence. He details a number of interesting facts, which seem to lead satisfactorily to the conclusion, that the mere exhalations from *putrefying animal matter*, however offensive to the senses, are never productive of fevers. The same inference has been deduced, not less satisfactorily, by Dr. Chisholm, in a very elaborate and able dissertation upon this topic, published in the *Edinburgh Medical and Surgical Journal* for October, 1810, vol. vi. p. 389. However contrary to the general opinion, this doctrine, that mere putrefaction is not the source of contagion and fever, appears, indeed, by these writers to be established. The experiment, in fact, has been tried on a large scale in France, in the case of the prodigious exhumations made in the church-yard of St. Eloi, at Dunkirk, in 1783, and in that of the saints Innocents at Paris, in 1786. In the latter case, nearly 20,000 bodies were taken up, in every stage of putrefaction, and a considerable part of the work was carried on during the greatest heats of summer, rendering the whole city offensive; yet no fever was occasioned by this immense mass of corruption. (See M. Thouret's *Memoir* in the *Journal de Physique*, for 1791, p. 253; and the *Annales de Chimie*, vol. vi.) The good health of nightmen, of persons living in dissecting-rooms, of those employed in the manufactory near Bath of a sort of spermaceti from putrefying flesh of all descriptions, and many other striking facts, detailed by the two authors just quoted, constitute a strong evidence in proof of the absence of insalubrity from mere putrefaction.

Dr. Bancroft next proceeds to prove, by another ample collection of facts and testimonies, that it is not the mere *aqueous vapour* that constitutes the morbid quality of miasmata. The principal proofs that mere moisture is incapable of producing these fevers, are, that sailors at sea for many months are generally very healthy; that no set of men are more uniformly so than the Newfoundland fishermen, who are usually enveloped in the dampest fogs for several months together; that while persons living on shore on unwholesome islands, as at Walcheren, are speedily attacked with fevers, those who remain on ship-board, at a little distance from land, entirely escape them; and that the occurrence of these fevers has been frequently prevented by laying swampy ground under water, under which circumstances the moisture of the atmosphere must be highly augmented.

Considering, then, that the mineral part of the soil is not vaporizable in any natural heat, and that animal substances

in a state of putrefaction are incapable of producing fever, as well as the mere aqueous vapour, Dr. Bancroft was disposed to conclude, that the morbid exhalations in question arise wholly from "the mutual decomposition of vegetable matters and water;" and that those swampy grounds are most likely to emit them, which contain the largest proportion of such matters, and in which the decomposition is most rapid and complete. This conclusion, he is of opinion, is confirmed by the facts that the exhalations from macerating hemp and flax are well known in Italy to produce fevers, and that those arising from heaps of decaying indigo, in the East and West Indies, have produced the same effects. See his *Essay on Yellow Fever*, above quoted.

Of the Treatment of Remittent Fevers.—As the violence of the symptoms, and consequently the actual character of these diseases, vary materially in different seasons, climates, and circumstances, under which they occur; so no uniform rule of treatment can be pursued for their cure. The same remedies, indeed, which at one period of the same fever are beneficial, are hurtful if resorted to at another. This observation, however, is applicable to all febrile diseases, and cannot be too often inculcated; since not only empiricism, but the routine of too many of the profession, tends to the appropriation of some leading remedy, whenever the name of a particular fever is mentioned: with some it is bark, with others antimony, and with others mercury; the indiscriminate use of any of which must be necessarily productive of injury.

In the more violent forms of the disease, which are common in hot climates, and in which the attack is marked by a sudden and severe affection of the head, with a hard, full, and strong pulse, indicating, with other symptoms, an inflammatory affection of the brain, perhaps the only remedy which is capable of arresting the disease, is speedy and free *blood-letting*. In the most violent forms of all, this evacuation should be resorted to very early, as within the first twenty-four hours, or the mischief will have advanced beyond the reach of this remedy. In milder cases, a moderate bleeding from the temporal artery or jugular vein, or even from the arm, within the first day or two, will often remove the danger and severity of the fever. The repetition and extent of the bleedings must be determined by a consideration of the violence of the symptoms, the duration of the disease, and the vigour of the patient. The notion that these fevers of hot climates are of a *putrid* nature, because they speedily run on to symptoms of debility, or putrescency, as they have been called, appear to be altogether erroneous; and it is now generally admitted, that the only effectual mode of preventing these symptoms, is by arresting the violent inflammatory excitement in the beginning, of which they are the immediate effect.

The next most effectual remedy, if resorted to also sufficiently early, is purgation. The purgatives administered should be such as in bulk and quality are not calculated to offend the stomach, which is usually in an irritable state: calomel, with jalap, answers the purpose well; and it is in all probability by its purgative quality alone, that mercury has been found beneficial in these fevers. The efficacy of mercurial purgatives, indeed, seems to have been fully established by the recent experience of our naval and military practitioners, in every quarter of the globe; while the mercurial practice, which had for its object the excitement of salivation, is shewn by Dr. Bancroft, from the testimony of Dr. Rush and others, its advocates, to have been by no means successful.

This early excitement is also considerably alleviated by the application of *cold* in every mode. Almost all the modern

den writers bear their testimony to the important auxiliary operation of the cold and tepid affusion; although they admit that, alone, its effects are not sufficiently powerful or permanent to be depended upon. *Coolness* of the patient is to be promoted by every means; by the free use of cold aqueous drinks, by frequent washing, by the full admission of fresh air, and by the use of few and light coverings on the bed.

These remedies should be actively employed, and repeated on the return or non-cessation of the symptoms of excitement. For as an intelligent physician has remarked, "the great object is the removal of the local affection of the brain, or other organ, and the production of a complete remission of the febrile symptoms, in the least possible time, by which the dangerous symptoms of the latter stages are prevented or greatly mitigated, and a perfect and rapid recovery insured." (See Dr. Burnett's Account of the Bilious Remittent Fever in the Mediterranean, p. 22. Lond. 1814.) This object is rather impeded, than assisted, by the administration of emetics and sudorifics; and altogether defeated by the use of bark, cordials, or stimulants of any kind, whether in the way of food or medicine. With respect to emetics, they are objectionable in all stages of the disease; for they not only fail in removing nausea, but actually increase that distressing symptom: their operation aggravates the affection of the head, of which the nausea appears to be sympathetic; and as the tendency of the disease is to augment irritability of the stomach, which often becomes extreme and distressing in the latter stages, so they contribute to aggravate this and other dangerous symptoms. Sudorifics are also to be condemned; for, in the first place, they are unnecessary, because a natural perspiration will readily ensue, as soon as the excess of heat above the standard of health has been removed, which can be accomplished with certainty by the proper application of cold water to the surface of the body; and, in the next place, the sudorifics which are used are apt to increase the irritability of the stomach; and if they fail to excite a diaphoresis, they increase the heat and the determination to the head, and tend to lengthen the paroxysm. With regard to the bark and cordials, they are invariably injurious in the first stage of the fever. When a distinct remission has taken place, some writers recommend the immediate administration of cinchona; but even these admit, that "if it be given when there is a parched skin, a hard pulse, a dry tongue, great heat and pain at the stomach, or delirium, it will generally be found to increase and prolong these symptoms." (See Bancroft, loc. cit. p. 76.) On the whole, however, the late experience in the Mediterranean led to the rejection of the use of bark, while any febrile symptoms whatever remained. "Under its use," says Dr. Burnett, "mortality has been great, relapse frequent, and (as in the cases of the Temeraire and Invincible) dysentery attacked nearly all the patients who had fever in a severe form; nor was there an instance, as far as I could learn, that, when given during a supposed remission of the symptoms, it prevented a return of the paroxysm. Too often it has been given with wine at the commencement of this disease, when the tongue has soon put on a brown, dry, and furred appearance; the anxiety, delirium, and irritability of the stomach, have been much increased; the whole train of nervous symptoms soon became formidable, resisting every means of alleviation, till death has put a period to the sufferings of the patient." Loc. cit. p. 34.

If any thing were wanting to corroborate the foregoing deductions from experience, in favour of the antiphlogistic and evacuant plan of treatment, in the commencement of

remittent fevers, the detail of the appearances observed on dissection, after the death of patients in these fevers, would amply support them, by the proofs which it affords of the inflammatory condition of various organs of the body in these fatal cases. In different instances, investigated by Dr. Burnett and his colleagues in the Mediterranean, the vessels of the brain were generally distended, and in many cases completely gorged with blood; the membranes of that organ were considerably inflamed, often presenting what that writer calls "a blood-shot appearance," and depositions of coagulable lymph were seen among the convolutions: there were occasionally also adhesions, and the ventricles were often distended with a fluid, sometimes limpid, sometimes yellow. Appearances of *high inflammation* presented themselves in the cavity of the chest, affecting the lungs, pericardium, and diaphragm; and these were connected with depositions of lymph and effusions of serum. In the abdomen, the liver was generally found enlarged, and sometimes exhibiting marks of inflammation; the stomach distended with air, more or less inflamed, and containing a dark coloured matter; and the intestines in a similar condition, with frequent intussusception.

These appearances, which are in fact the effect of the continuance of the febrile actions in the organs in question, sufficiently prove that the first stage is the time when active remedies, of an anti-inflammatory power, can be chiefly expected to produce a very decided removal of the disease. When the fever is a little more advanced, the principal object of the practitioner is to diminish the violence of any local affection that may be severe. Thus, if head-ache remains, with flushed countenance, suffusion of the eyes, and a firm pulse, a small bleeding from the temporal artery (the pulse being at the same time carefully examined) may be employed with advantage: a blister, applied to the head at this time, is also manifestly beneficial; and daily evacuations of the bowels should be procured by gentle laxatives, such as castor oil, or glysters, the powerful cathartics being now laid aside. Irritability of the stomach, which is often distressing at this period, is relieved by the effervescent draught, and by the application of leeches, or of a large blister to the pit of the stomach. A degree of stupor sometimes supervenes, which is often removed by a blister applied to the neck or forehead, or by the application of leeches to the temples. If there is any obvious affection of the abdominal viscera, which should be carefully inquired into, blisters, and, above all, the warm bath, should be resorted to, as well as copious emollient glysters.

If, however, from want of the means of relief, or from the violence of the disease, it has advanced to that stage, in which the yellow suffusion of the skin appears, and various nervous symptoms, subsultus, tremors, &c. come on, with increased uneasiness about the stomach, hiccup, or vomiting of a dark matter, resembling coffee-grounds, with ischuria, and a sinking or intermission of the pulse, little more can be done than to look on, and endeavour to obviate symptoms as they occur. "Singultus," to borrow again the words of Dr. Burnett, "is a dangerous, and commonly a most harassing symptom at this time: it will often be relieved by camphorated julep, to which may be added opium and æther. If the pulse sink, the stimuli must be increased; and under these circumstances, I have found the carbonate of ammonia, with aromatic confection, of singular benefit. But while we endeavour to restore the circulation, care must be taken not to induce a state of secondary excitement; and as the pulse rises, the stimuli should be decreased. Constant attention must still be paid to the daily evacuation of the bowels; but at a period, when the excitability of the system

tem is nearly destroyed, powerful cathartics will be attended with the most deleterious consequences: glysters are particularly serviceable at this time. As the disease advances, the secretions are at times voided involuntarily: in a few I have observed a retention of urine, and in these last cases the catheter should be used; but as a general symptom, there is far oftener a deficiency in the secretion of that fluid. Frequently in this state, the stomach rejects every thing. We may now safely indulge the patient *moderately* with any thing to which his fancy leads him. Bottled porter, wine, and brandy and water, have been found beneficial. But no remedy can be relied on with any degree of certainty: whatever calms the irritability of the stomach, and moderately supports the excitability of the system, is useful. A few spoonfuls of arrow-root or sago, with wine and spice, given occasionally, will often be retained by the patient, and greatly at this period assist the cure." Burnett, loc. cit. p. 29.

During the *state of convalescence* at every period, whether from a complete remission being procured early, or from a gradual cessation of the disease, extreme caution is necessary in regard to preventing repletion: in the former case, it is apt to induce a relapse; and in the latter, it will retard the cure. During the whole progress of recovery, attention should be paid to the regularity of the bowels. Some light tonic, as an infusion of quassia, gentian, or cinchona, with an aromatic or sulphuric acid, may be administered. When the yellow suffusion of the skin has been great, a protracted convalescence is commonly the consequence; and is often attended with irregular affections of the bowels, and symptoms of indigestion. In these cases, small doses of the mercurial pill, with an occasional gentle purgative of castor oil or rhubarb, are very beneficial. It is almost exclusively, indeed, in these protracted cases, where a morbid affection of the liver, brain, or some other viscera, has been the result of the uninterrupted violence of the first stage of the fever, and especially when there is reason to suppose that assuision had taken place within the cranium, that mercury, in small doses, is of any actual utility. Small doses of calomel, or of the pilula hydrargyri, should be administered until some sensible, but slight, effect be produced on the salivary system; after which the disease often ceases of itself, or is readily removed by the use of the Peruvian bark. See Burnett on the Bilious Remittent in the Mediterranean; Bancroft on the Yellow Fever; and Irvine on the Diseases of Sicily. See also FEVER, *Yellow*, and MIASMA.

REMITTENT *Fever of Children*, the *febris infantum remittens* of Dr. Butter, which is a very common affection of children, when the abdominal organs are deranged, has already been described at length, under the head of INFANTS, § 5. *Febrile Diseases of*; which see.

REMITTER, in *Law*. Where a man has two titles to land, and is seized by the latter; and, that proving defective, he is remitted or restored to the former more ancient title; this is called a *remitter*, from the Latin, *remittere*, to send back.

If land descend to him that had right to it before, he shall be remitted to his better title, if he please. 1 Inst. 347. b. Litt. § 659.

Remitter is classed (with *retainer*) by judge Blackstone, among those remedies for private wrongs, which are effected by the mere operation of law, and is thus described: remitter is where he, who hath the true property or *ius proprietatis* in lands, but is out of possession thereof, and hath no right to enter, without recovering possession in an action, hath afterwards the freehold call upon him by some subsequent, and of course defective title: in this case, he is re-

mitted, or sent back, by operation of law, to his ancient and more certain title. (Litt. § 659.) The right of entry, which he hath gained by a bad title, shall be *ipso facto* annexed to his own inherent good one; and his defeasible estate shall be utterly defeated and annulled, by the instantaneous act of law, without his participation or consent. (Co. Litt. 358. Cro. Jac. 489.) As if A disseises B, that is, turns him out of possession, and dies leaving a son C; hereby the estate descends to C, the son of A, and B is barred from entering thereon till he proves his right in an action: now, if afterwards C, the heir of the disseisor, makes a lease for life to D, with remainder to B the disseisee for life, and D dies; hereby the remainder accrues to B, the disseisee; who thus gaining a new freehold by virtue of the remainder, which is a bad title, is by act of law remitted, or in of his former and surer estate. (Finch. L. 194. Litt. § 683.) For he hath hereby gained a new right of possession, to which the law immediately annexes his ancient right of property.

If the subsequent estate, or right of possession, be gained by a man's own act or consent, as by immediate purchase being of full age, he shall not be remitted. For the taking such subsequent estate was his own folly, and shall be looked upon as a waiver of his prior right. (Co. Litt. 348. 350.) Therefore it is to be observed, that to every remitter there are regularly these incidents; an ancient right, and a new defeasible estate of freehold, uniting in one and the same person; which defeasible estate must be *cast upon* the tenant, not gained by his own act or folly. The reason given by Littleton (§ 661.), why this remedy, which operates silently and by the mere act of law, was allowed, is somewhat similar to that given under the article *RETAINER*; because otherwise he who hath right would be deprived of all remedy. For as he himself is the person in possession of the freehold, there is no other person against whom he can bring an action, to establish his prior right. And for this cause the law doth adjudge him in by remitter; that is, in such plight as if he had lawfully recovered the same land by suit. For, as lord Bacon observes (Elem. c. 9.), the benignity of the law is such, as when, to preserve the principles and grounds of law, it depriveth a man of his remedy without his own fault, it will rather put him in a better degree and condition than in a worse. *Nam quod remedio destituitur, ipsa re valet; si culpa absit.* But there shall be no remitter to a right, for which the party has no remedy by action (Co. Litt. 349.); as if the issue in tail be barred by the fine or warranty of his ancestor, and the freehold is afterwards cast upon him; he shall not be remitted to his estate tail. (Moor. 115. 1 Ann. 286.) For the operation of the remitter is exactly the same, after the union of the two rights, as that of a real action would have been before it. As, therefore, the issue in tail could not by any action have recovered his ancient estate, he shall not recover it by remitter.

The determination of the law, according to the doctrine of remitter above stated, might seem superfluous to an hasty observer; who perhaps would imagine, that since the tenant hath now both the right and also the possession, it little signifies by what means such possession shall be said to be gained. But the wisdom of our ancient law determined nothing in vain. As the tenant's possession was gained by a defective title, it was liable to be overturned by shewing that defect in a writ of entry; and then he must have been driven to his writ of right, to recover his just inheritance: which would have been doubly hard, because, during the time he was himself tenant, he could not establish his prior title by any possessory action. The law, therefore, remits him to his prior title, or puts him in the same condition as

if he had recovered the land by writ of entry. Without the remitter, he would have had *jus, et seisinam*, separate; a good right, but a bad possession: now, by the remitter, he hath the most perfect of all titles, *juris et seisinæ conjunctionem*. Blackf. Com. b. iii.

REMLINGEN, in *Geography*, a town of Germany, in the county of Wertheim; 9 miles E. of Wertheim.

REMNEY, or REMPNEY, a river of Wales, which rises in Brecknockshire, and, after separating the counties of Monmouth and Glamorgan, falls into the mouth of the Severn, a little below Cardiff.

REMOLADE, in the *Manege*. See CHARGE.

REMOLLAN, in *Geography*, a town of France, in the department of the Higher Alps, on the Durance; 15 miles S.W. of Embrun.

REMON, a township of Upper Canada, on the St. Lawrence; N. lat. 44° 50'.

REMONSTRANCE, an expostulation, or humble supplication, addressed to the king, or other superior, to beseech him to reflect on the inconveniencies, or ill consequences of some order, edict, or the like.

REMONSTRANCE is also used for an expostulatory counsel or advice; or a gentle and handsome reproof, made either in general or particular, to apprise or correct some fault.

REMONSTRANTS, REMONSTRANTES, a title given to the Arminians, by reason of the *remonstrance* they made, in 1610, to the states of Holland, against the synod of Dort, in which they were condemned.

Episcopius and Grotius were at the head of the Remonstrants. And as the patrons of Calvinism presented an address in opposition to their remonstrance, which they called their counter-remonstrance, they received, in consequence of this, the name of "Counter-remonstrants."

REMONTER, Fr. in *Musick*, to new-string an instrument.

REMONTOIR, or REMONTOIRE, in *Horology*, is a species of escapement, in which a secondary spring frequently wound up, or a small secondary weight frequently raised, by means of the maintaining power of a watch or clock, is substituted for the maintaining power itself, for the purpose of urging the balance or pendulum, at short intervals, by more equable impulses than can be constantly effected by the maintaining power alone, as varied by different degrees of friction in the train. When treating of ESCAPEMENTS in general, under their appropriate head, we described three only out of the four classes, and reserved the fourth class, denominated *Remontoir*, till we arrived at our present article.

The first remontoir was invented and made by a German artist in 1600, according to Berthoud; but Huygens, who applied one to his marine clock, described it first in his "*Horologium Oscillatorium*," page 17, and, in conjunction with his cycloidal cheeks, it promised to be a great improvement in his machine; but, as no compensation had at that time been applied to the pendulum, and, as a pendulum is not calculated for a portable machine, particularly on the sea, the utility of the contrivance remained to be proved by subsequent artists. The contrivance under our consideration was a small weight, suspended by an endless well made metallic chain, that was coiled round the crown-wheel of the escapement, and wound up a small space, at every vibration of a half-second pendulum, by the next wheel, which wheel took its motion from the maintaining power, through the medium of the train, as is usual in common clocks; a ratchet and click, however, were a requisite appendage, to act in the way that the endless cord was applied, in winding up the maintaining power without stopping the motion of the works; such as we have already described in the fifth section of our article

CLOCK-WORK. One half of the weight of the remontoir actuated the escapement wheel during its small fall, and the other half was supported by the wheel that as often raised it again to its original height, while both parts of the folded chain were stretched alike by the said weight. Leibnitz and Dr. Hooke also claimed the originality of a similar invention, but do not appear to have put it in practice, as Sully afterwards did.

Mr. Harrison and Mr. Mudge successively applied remontoir springs, instead of suspended weights, to the escapements of their time-pieces; but, as we have described these under our article CHRONOMETER with sufficient minuteness, it is not necessary to repeat here what we have there detailed of their constructions.

Mr. Cumming and Mr. Nicholson, on the contrary, had recourse again to weights instead of springs in their astronomical clocks; but as these weights did not act during the whole period of the vibration, we have already described them in another class, in the 21st and 38th sections of our ESCAPEMENTS.

After Huygens and Sully, who left no plans of their mechanism behind them for the advantage of future workmen, who had not access to the original machines, Gaudron contrived a remontoir, which performed its office very well, but which was applied in a wrong place, so as not to produce the desired effect of equalizing the impulses given to the regulator; for, instead of being applied to either the balance or balance-wheel, it was made to actuate the wheel preceding the minute-wheel; and, therefore, permitted the irregular friction of a considerable portion of the train to affect the motions of the balance, which fault was avoided in the construction of Harrison's and Mudge's time-keepers: the former of which had its secondary spring wound up eight times in every minute, and the latter had its two remontoir-springs alternately coiled at every corresponding oscillation.

Haley's.—In the year 1796, Mr. Charles Haley, of Wigmore-street, Cavendish-square, London, watch-maker, took out a patent for his invention of a new remontoir spring for a marine time-piece, or chronometer; the specification of which is contained in the 6th volume of the *Repertory of Arts and Manufactures*. Figs. 1 and 2, of *Plate XLI. of Horology*, exhibit, the first a perspective side view, and the second a plan of Mr. Haley's remontoir escapement, as originally drawn; and we propose to retain the same letters of reference as are inserted in the original description. The utility of the invention is stated to consist of its property of communicating an invariable force to the balance, which it does 150 times in the minute, in a train of 9000 beats in the hour. The same letters of reference apply to both figures, and indicate the corresponding parts, which will mutually illustrate each other. A B is the potance plate, and T the balance, the pivots of which, P, X, turn in the cock C and potance D; above the balance T is fixed a pendulum spring S, in the usual way; on the axis of the verge, below the balance, are placed two small steel collets I and K, by friction, having each a ruby pallet projecting a little way beyond their surfaces. I is called the discharging pallet, and K the impelled one; which pallets, together with the pendulum spring, all vibrate with the balance, whenever it is put in motion. E is the balance-wheel of the usual form, moving just clear of the potance plate, and having its pivots supported by the cocks F and G. W V is the axis of the remontoir, which the inventor calls the *renovating* spring; and the three axes, or arbors, just described, stand in the straight line in the direction A B. Below the remontoir spring the round steel pallet M is fixed, so as

just to escape touching the ends of the balance-wheel's teeth in its resting position, and the notch cut in this pallet is to receive the impulse of any tooth of the said wheel that may, at any time, act against it, in passing the line A B. Just above this large pallet is fixed, by friction, another smaller pallet N, of steel, in the form of a snail-piece, and having inserted into it, near the centre of motion, and at right angles, a small ruby pallet, which points directly to the radial end of the notch cut in the large pallet M. A small collet, twisted fast to the axis of the remontoir, just above this snail-pallet, receives the lower end of the spring R, while the upper end is made fast to a piece in the cock H, near W, in a manner similar to that by which the pendulum-spring is fixed. On the arbor of the remontoir, and under the plate A B, is twisted on a pallet I, which may be called the remontoir's impelling pallet, because it gives motion to the balance by striking the pallet K, which the author also called the *impelling* pallet; but is, as we have named it, more properly the *impelled* pallet, because it *receives* the impulse which pallet I imparts. From this detail of the pallets it is obvious, that whenever the balance-wheel impels the large pallet M, the remontoir-spring R, the snail-pallet N, together with its small ruby pallet and impelling pallet I, must have a contemporary motion, and will describe each its respective circle round the common arbor W V.

In *fig. 2*, *a* is a detent-spring, fixed by a screw and steady pin to the upper face of the potance plate, and pointing directly to the axis of the verge, which it nearly approaches. Its shape and mode of being fixed will be better understood from an inspection of *fig. 3*, which gives a side view of it, and from which it will be seen that it is placed high enough above the plate, to come in the way of the discharging pallet I, in each revolution of the latter. Upon the side of the said detent-spring *a*, next to the balance-wheel, a second, but very slender spring is pinned, so that its projecting end exceeds that of the detent-spring, and comes nearer to the balance verge than that of the detent, as represented at *m*, in *fig. 3*. To the detent-spring is made fast a small ruby pallet *r*, seen also in *fig. 3*. The cock *b* is screwed to the potance, and the hole at *i* is tapped to receive the screw *c*, the head of which, being turned towards the centre of the snail, forms a banking for the detent-spring *a*, when struck by the snail-pallet. This screw, *c*, is removed from its due place in the drawing, to avoid confusion; and for a reason, which will presently appear, this double spring *a* may be called the remontoir-detent. On another side of the balance-wheel a second detent-spring *d* is fixed, pointing towards the centre of the remontoir axis, and forming nearly a right angle with the former detent: this second detent is adjusted by the screw *y*. The shape and situation of this second detent, which may be called the locking detent of the balance-wheel, is better seen in *fig. 4*, where its sapphire pallet *s* may be distinguished, against which the tooth 3 of the wheel is supposed to be resting in *fig. 2*. The situation of this pallet *s*, as adjusted by the screw *y*, determines the resting-places of the teeth 1 and 2, while they are equally free from the edge of the pallet M. The locking detent *d* is likewise made fast by a screw to the upper face of the potance plate; and the screw *f*, placed in the cock *e*, but out of its place in the figure, forms a banking to the sapphire pallet *s*, while the screw *g*, in a smaller cock, limits the excursion of the detent-spring *d* itself.

Having described the various pieces of mechanism that compose this remontoir escapement, we will now proceed to explain its mode of acting. First, let us suppose all the parts at rest with the wheel locked by the pallet *s* last described, but that the wheel is ready to move in the direc-

tion of the arrow Z, by the action of the main-spring, through the train, whenever the single detent *d* is by any force impelled back to its banking. Let it also be conceived that, when the snail-pallet N is carried by any means in a direction contrary to that of the wheel till it reaches the pallet *r* of the remontoir or double detent-spring, the remontoir-spring is wound up by such motion, and *vice versa*, and also that when the stroke of the snail-pallet has driven back this detent to its banking, by striking the sloped face of the ruby pallet *r*, the detent will instantly return by the force of its elasticity, and the back part of the said ruby pallet *r* will hold the snail-pallet locked at its return, till some other impulse sets it free again; but that when the unlocking takes place, the spring of the remontoir, now wound up, returns by its own force to its original situation; and that its axis brings back with it its affixed pallets.

Fig. 1. will be of no use in describing the action of this escapement, but in *fig. 2*. the parts are represented in a state ready to commence motion; the wheel is locked by tooth 3 against the sapphire pallet *s* of the single detent *d*, and the remontoir-spring is wound up, and kept locked by the snail-pallet, resting behind the ruby pallet *r* of the double detent: in this situation let the balance be wound round in such direction that the discharging pallet I may strike the end of the double or remontoir detent outwards, taking both its springs along with it, and thereby unlocking the snail-pallet; at this instant the remontoir-spring R begins to return, and brings all its four pallets with it, and during the return, pallet I, which we have called the impelling pallet, gives its stroke to pallet K on the verge, which we have called the impelled pallet, and through its medium to the balance itself, which now goes on in its oscillation, till the pendulum or balance-spring is wound up; in the mean time the little unlocking ruby pallet, inserted into the snail-pallet near its centre of motion, meets with the extreme end of detent *d*, and drives it back to its banking, thereby setting the tooth 3 of the wheel free from the sapphire pallet *s*; the wheel, being urged by the train, now proceeds till tooth 2 falls into the notch of pallet M, and is checked, experiencing a little recoil; the balance-spring, being now wound up, returns, and also the wheel winds up the remontoir-spring, till it is again locked, by the snail-pallet, after its impulse has driven back the detent: during this action the detent *d* returns by its own spring, and locks tooth 4 of the wheel, at the instant that tooth 2 escapes from the notch of pallet M, and the original situation of all the acting parts is now restored, except that the motion of the balance is not arrested, the slender spring fixed to detent *a* allowing it to pass in the return, without unlocking the said detent; but when the backward oscillation is finished, and the balance returns, the same operation is repeated; *i. e.* the remontoir detent is unlocked, the pallets on its axis are brought back, the impulse is next given to pallet K of the balance, to restore its loss of momentum, and lastly, the wheel is unlocked to wind up the remontoir-spring as before.

The observation we have to make on this ingenious remontoir escapement is this, that on enquiry from good authority we learn, that the theory could never be completely put into practice by the inventor, though he laboured to obtain his object full fourteen years. However well the parts of action were mechanically made, the locking of the remontoir-spring was never certain, for the *flirt* given to the ruby pallet *r* by the snail-pallet, drove back the detent so far, as frequently to enable the snail to be brought back by the remontoir-spring, before the detent returned to catch it, the consequence of which was, that the pallets of the remontoir axis were all brought back, and the impulse vainly ex-

perded by pallet L, before the pallet K of the balance returned to its place to receive it. Mr. Hardy, however, has lately contrived a species of locking that is quite certain, as well as safe, which we shall presently have occasion to describe.

Breguet's.—We have not been able to ascertain the exact date of the French watch-maker Breguet's invention of a remontoir escapement, but as Berthoud has placed it after Haley's in his "Histoire de la Mesure du Temps," we must conclude that it is of more recent origin. The mechanism is so complex, that the description given in the French work is divided into three parts, which plan we propose to follow.

Figs. 5. and 6. of Plate XLI. of Horology, will suffice to explain the different parts of Breguet's remontoir; *fig. 5.* being a plan of the whole, and *fig. 6.* exhibiting a perspective view of such parts as could not be well understood without such representation. The first portion of the mechanism consists of two wheels of unequal numbers of teeth, with their planes in contact, and revolving on one common arbor concentrically, namely, the wheel B B', and the wheel D, the first having many teeth and a larger diameter, and the second having few, for a reason which will appear hereafter: these wheels are actuated by a pinion *g*, connected with the train, and having just so many leaves as there are teeth in the large wheel B B', contained in the space between two contiguous teeth of the small wheel D; on the arbor of this pinion, near the pivot, is inserted a fly with unequal arms, represented by the letters *igb* in both figures, the longer arm of which, *gb*, is armed with a piece of steel of peculiar shape, seen in *fig. 6.* A spring-detent *r F*, made fast to the cock at *r*, lies at right angles to the fly, when in a state of rest, and has a ruby pallet V at about one-third of its length from its interior end, which stops the fly by opposing its end *b* near *o*, and consequently prevents the train from urging the double wheel, so long as no force unlocks the pallet from the end of the fly; but if any impulse happen to bend the detent in a direction towards the pinion *g*, then the ruby pallet slips through a notch made in the steel part of the fly, and the fly makes an entire revolution, while the pinion revolves and urges the large wheel the space of as many teeth as the pinion contains; that is, a space corresponding to the distance between two contiguous large teeth in the small wheel, which wheel also moves the same quantity, before the fly is again opposed and stops.

The second portion consists of the following parts; a spring G, curved at the interior, or moveable end, serves at the same time for a remontoir-spring, and also for a pallet to give the impulse to the balance; it has consequently a heel-piece *n*, by which it is urged into a state of tension by the small wheel D, at every revolution of the fly, and also a ruby pallet *m*, with a locking notch cut in it; *a H*, made fast at *a*, is a detent-spring, placed nearly at right angles to the spring G, and having a slender spring N made fast to its side; this detent-spring carries a small ruby *p*, which locks into the notch of the piece *m* in the spring G, when this is in a state of tension. Another ruby, inserted into the extreme end of the detent *a H* at *s*, is so placed, that the slender spring N can move from right to left without impediment, but when urged in an opposite direction against the ruby *s*, it takes the large or detent-spring along with it, and unlocks the remontoir-spring G, by removing the small ruby *p* from the notch of *m*. The detent-spring H has at its extreme end a claw, against which the ruby *m* falls when this detent escapes back from a tooth of wheel D; and this claw has a pin in it, against which the slender spring N rests; again, at the extreme end of the slender spring N are fixed two parallel chamfered plates, so contrived,

that any pressure made on the upper slope, or inclined edge, will depress the spring, but a similar pressure made on the under slope will elevate it again, the downward pressure being employed to disengage the ruby *m* from the claw, and the contrary.

The third portion consists of the pieces or pallets K and *b*, borne by the superior end of the verge of the balance, and fixed at a quarter of a circle from each other. When the oscillation of the balance is from right to left, or in the direction from *b* to K, the unlocking pallet piece K, in its motion, bends the slender spring, and passes over it, but as the pallet *b* is placed above the plane of the wheel B B', and under the spring H, this oscillation from right to left is performed in freedom, except that the slender spring N requires to be a little bent out of the way; but when the oscillation is made from left to right, the pin at H presses this slender spring against the ruby *s*, the spring H then gives way, and bending, allows the ruby *p* to escape from the notch at *m*, and the spring G, being unlocked, is at liberty to perform its office, which we now proceed to describe.

The action of these three portions of the mechanism may be thus explained: at the instant that the ruby *p*, in the detent *a H*, is disengaged from the notch at *m* in the remontoir-spring G, the pallet *b* of the balance is found pointing towards the common centre of the wheels, and ready to receive an impulse from the extreme end *q* of the curved part of the remontoir-spring G, which end now gives its stroke to the balance through the medium of pallet *b*; immediately after which stroke, the same end *q* proceeds till it falls on the end F of the fly's detent, to which it now gives a push, and remains quiet; this push unlocks the fly, as has been before explained, and an entire revolution is immediately performed by it, while its pinion *g*, now at liberty to advance, urges on the double wheel, till another tooth in the small wheel, catching the heel-piece *n* of the remontoir-spring, puts this spring again into a state of tension; and the ruby *p*, falling into the notch of *m*, locks it as before, the balance in the interim completing its oscillations: and in this manner the operation is repeated.

De Lafon's.—In the year 1801, the Adelphi Society for the Encouragement of Arts, &c. rewarded Mr. John de Lafon with thirty guineas for his invention of a new remontoir watch escapement, which comes next under our notice. *Figs. 1 and 2 of Plate XLII. of Horology,* are a plan and section of this escapement, as given by the inventor in the Society's Transactions of the year above-mentioned. In both these figures, A is the escapement wheel; B, the lever-pallet on an arbor with fine pivots, which has, at its lower end, the remontoir spiral spring C, fixed with a collar and stud in the usual way; D is the pallet of the verge, having a roller turning in small pivots, for the lever-pallet to act against without friction; at E are the pallets for discharging the locking, with a roller between, containing a small notch; F is the arm of the locking pallets, continued at the other end beyond the centre of motion, to preserve the equipoise, and having studs and screws for adjustment of the banking; *a* and *b* are the locking pallets, being portions of circles fastened on an arbor, turning on fine pivots at the midway between the pallets; G is the triple fork, at the end of the arm of the locking pallets. In *fig. 1*, tooth 1 of the wheel having caught the interior end of the lever-pallet B, has urged it forwards and wound up the remontoir-spring, and the instant that the verge pallet D comes nearly in contact with the remote end of the lever-pallet, the discharging pallet E, taking one prong of the fork, removes the arm F, thereby relieving the tooth 3 from the convex part of the claw *a*, that locks the wheels.

REMONTOIR.

The wheel now advances a little way, just enough to allow the interior end of the lever-pallet to pass back again, as urged by the spiral spring, while the remote end of the said lever gives an impulse to the balance, through the pallet D; the tooth 4 is then locked on the concave side of the locking claw *b*, and the interior end of the lever-pallet partly supports the following tooth; in this situation the oscillation is finished, and on the return of the balance pallet E, striking the prong of the fork in a contrary direction, again unlocks the wheel from claw *b*, while the force of this wheel is partly suspended by the end of the lever-pallet; being now at liberty, the wheel proceeds to wind up the remontoir-spring again, till another tooth falls on the claw *a*, now brought inwards, when the operation is completed, and the pressure of the inner end of the lever pallet against its contiguous tooth again relieves the claw *a* from a part of the pressure of the wheel, and thereby renders the unlocking as easy as before, when claw *b* was unlocked. This escapement appears to us an improvement on Haley's, both as to its simplicity and safety of locking, and the inventor proposes a still further simplification, by substituting a straight remontoir-spring for the spiral one, particularly in time-pieces intended to remain in a stationary situation, where the weight of the spring would form no objection; but it does not appear that such construction was ever adopted. The simplicity of the locking of the remontoir-spring by the wheel itself, where this spring and the maintaining power mutually re-act, requires, as might be foreseen, an unusually strong maintaining power, which is, perhaps, one of the greatest objections to this mode of applying the remontoir; unless, indeed, what was remarked by the society's committee be true, that the balance must vibrate in a large arc before the piece will continue to perform.

Maffey's.—Mr. Edward Maffey, of Hanley, in Staffordshire, received a reward of fifty guineas from the Adelphi Society, in the year 1803, for his invention of two different clock escapements, one of which we have already described, under our article ESCAPEMENT, as being without a verge; and the other we shall make the subject of our present section. *Fig. 3. of Plate XLII.* represents so much of Maffey's remontoir escapement as is sufficient to explain all the essential parts; in which A is the swing-wheel; B, C, are two detached pallets, moving on separate arbors, at opposite sides of the swing-wheel; B is seen urged by the remontoir-spring E, by the aid of a tail-piece fixed on the arbor of pallet B, which receives the action; and the other pallet must be conceived to have a similar spring and tail-piece, which cannot easily be represented in the drawing; F is the verge bearing two arms without pallets, which press under the pins of the detached pallets, and raise them alternately, at each vibration of the pendulum, from the teeth of the swing-wheel, which had been previously impelled by the maintaining power, and K is the pendulum suspended in the usual way, and having a crutch to communicate its force to the verge at the moment of withdrawing the pallets. All, therefore, that the pendulum has to do, is, to disengage the pallets from the teeth of the swing-wheel that locks against the inclined planes of the pallets; for the remontoir-spring then opposes the ascent of the pendulum, and aids its descent, by means of the connection between the pins of the pallets and the arms of the verge, which must, from the nature of the construction, continue in contact during a large portion of each excursion of the pendulum. It is not stated in the author's account (*Trans. Adel. Soc. vol. xxi.*) at what part of the arc of vibration the pendulum unlocks

either of the pallets, but it seems to us capable of being made to effect this office at its point of *greatest velocity*, if it does not do that as now constructed. An attention to this particular is of the utmost importance in any escapement, since the natural law of gravity is the least deranged, when any force is given, or taken away, when the pendulum is at the *lowest point* of its arc, for the velocity it has at *that point* determines the height to which the ball shall rise; but any addition or diminution of the pendulum's momentum, beginning at any other point of the arc, either adds to, or diminishes the natural length of the vibration, and injures the isochronism. Besides, a spring commencing both its accelerating and retarding influence at the point of the pendulum's greatest velocity, acts, not only by a law commensurate with the law of gravity, but their various forces, thus exerted, are contemporary, and, therefore, act together as one; a consideration which never should be lost sight of in the construction of an escapement of any denomination. The principal advantages that the author seems to insist on in this escapement, are, that the friction is diminished at the acting parts of the pallets, the impulse being given by a direct *push*, without, or with very little, sliding motion; and that a certain regular momentum is kept up in the pendulum, independently of any variation which may occur in the wheel-work, or in the acting part of the pallets during the short time of unlocking; but, what is the principal object of such a contrivance, he has not stated, perhaps not considered, how this *certain regular momentum* is, or ought to be, *modified*.—Indeed, in speaking of his other escapement without arbors, he says, that one of its advantages over this is, that during a *part* of the vibration the pendulum is *disengaged*; from which remark, it should seem, that he thinks the constant action of this remontoir-spring, however modified, an objection to be avoided.

Antis.—In vol. xxiii. of the Transactions of the Society last mentioned, it is stated, that Mr. John Antis of Fulneck, near Leeds, sent this society a model of a new clock escapement in 1805, with a corresponding description, for which a reward was voted him of twenty guineas. The model is deposited in the room at the Adelphi appropriated for the reception of models, but as the description is not published in the Transactions of the Society, nor an engraving given of the model, we must infer, that the contrivance either is not new, or is not of such importance as to merit the particular notice that has been given by them to the inventors of like contrivances, who both preceded and followed him. Indeed, in the letters of Mr. Antis to the Society, published with their account of the rewards, it seems that two escapements were sent them, one a *detached* one, and the other, one that “*would equalise the power of the impulse*,” which must, therefore, have been of the *remontoir* description; but he confesses that these contrivances by him “*may have been practised before*.” With respect to the latter escapement, he remarks, what is worthy of being recollected by clock-makers in general, that, by its means “*a spring-clock will be as perfect as one which goes by weight, and more so if the latter has no remontoir*.” Should any of our readers have a wish to see and examine Mr. Antis' productions, which, he acknowledges, are done in a rough manner, and under disadvantageous circumstances, but which may not be the less ingenious on that account, there will be no difficulty in gaining admission to the model room, where the original work is preserved with a view to public inspection, provided the applicant be properly introduced.

Mendham's.—It frequently happens that considerable
4 Q 2
improve-

improvements are made in mechanical contrivances, by men whose principal employment has no connection with the art to the improvement of which they contribute; this was probably the case with Mr. Antis, and is confessedly so with Mr. Mendham, who was rewarded with the silver medal of the Adelphi Society, in the year 1807, (see vol. xxv.) for a remontoir escapement for a chronometer, which next offers itself for our description. *Figs. 4, 5, and 6, of Plate XLII.* are copied from the plate given by Mr. Mendham, *fig. 4.* being a section of the whole escapement, *fig. 5.* a plan of the wheel and locking pallet, and *fig. 6.* a detached view of the pallets and their common arbor. The letters *a a*, in *fig. 4.* are the two plates of the frame that contain the works; *b* is the balance, nearly of the usual shape and size; *c* is the pallet that acts with the wheel, and *d* its arbor; *e* is the locking single spring; and *f* is the unlocking pallet in the form of a pin, attached to *e*, and seen better in *fig. 6.* At the lower end of arbor *d* is placed *g*, the remontoir-spring, that gives force both to the small pallet *f*, and also to the perpendicular pin *h*, that forms a part of the pallet *c*. The arbor *d* does not ascend above the upper plate of the frame, but the pin *b* does, and the plate being formed, as we suppose, like a rim, *b* is permitted to move in the vacant space within the rim, and sufficiently high to fall in the way of the finer pin *l*, inserted into and under the balance. The balance *i* has its verge immediately over the upper pivot of arbor *d*, point to point nearly, so that the motions of the balance-pin *i*, and of the pin *h*, that impels it, may be concentric. The cock *k* supports the upper pivot of the verge, and also holds the outer end of the balance or pendulum-spring. The action of these parts may be thus explained; before motion is given to the balance, we must conceive its pin *i* to be in contact, or nearly in contact with the pin *h* of the pallet *c*, and it must be remembered, that the wheel rests on the pallet during the vibration of the balance: suppose now that the remontoir-spring *g* is in the act of being wound up by the balance-wheel, as actuated by the train; and that the pin *i* of the moving balance has kept in contact with the impelling pin *h*, borne by the arbor of the remontoir, it is evident, that the force of the remontoir-spring is here opposed to the momentum of the balance and at last stops it, thereby forming a banking of an unlimited extent; but the tooth of the wheel in contact with pallet *c*, at the point of shortest radius, assists to oppose or wind up the said spring during a space of one-fifth of a circle, till the tooth has passed and the wheel is locked; on the return of the balance the remontoir-spring exerts all its force on the balance, but without a jerk, the pins *i* and *h* being already in contact, till it comes to the stop; the balance then maintains its motion, and the small pallet *f* having unlocked the wheel by forcing out the detent, the next tooth of the wheel falls on the pallet *c*, and waits the return of the balance, when the same operation is repeated.

Mr. Ramsay of Islington was consulted on the merits of this escapement, and, on considering its properties, he gave a written report to this effect; that the impulse is here given to the balance without friction, exactly as in Mudge's chronometer; and that the remontoir is wound up by the maintaining power in a similar way, except that the shape of Mudge's tooth limited the quantity of tension of the spring, which here depends on the amount of the maintaining power; but that this escapement, having but one remontoir-spring, is more simple than Mudge's, and allows an unlimited arc of vibration, which advantages compensate the foregoing disadvantage in the shape of the tooth; and lastly, that it is superior to the detached escape-

ment, inasmuch as that it gives the impulse without friction.

G. Prior's.—The silver medal and twenty-five guineas were voted to Mr. George Prior, junior, of Otley, in Yorkshire, in the year 1809, by the Adelphi society (vol. xxvii.) for his invention of a new clock escapement, in which an impelling (not however called a remontoir) spring actuates, or professes to actuate, the pendulum at each alternate vibration. The account, particularly of the action, as printed in the society's Transactions, seems to us so extraordinary, that we beg leave to transcribe it verbatim, in order to make some remarks on it, that may enable the reader to judge of the escapement's peculiar qualities, or at least of the manner in which they are described. *Fig. 7.* of *Plate XLII.* already referred to, contains enough of this escapement to answer the purpose of the description in question, and therefore we will omit the references to *fig. 1.* in the original plate, and attend to its *fig. 2.* only. "*Fig. (7)* is a back view, which is supposed to be taken from behind the clock; *a* represents the axis of the swing-wheel, or last wheel of the train of the clock; *b d* is the swing-wheel fixed upon it, having thirty serrated teeth; it is turned round, in the direction from *b* to *d*, by the maintaining power of the clock; *g* is a spring-detent, which locks against one of the teeth of the swing-wheel, and this prevents its running down by the action of the maintaining power; *h* is another spring-detent, which is called the impelling spring; when left at liberty, it unlocks the former, by pushing against the end of the small arc *e*, fastened to the detent *g*, and thus removing the end of the detent which obstructed the wheel's motion; *l* is the rod of the pendulum, suspended by a cock screwed to the back plate of the clock; a small piece of brass, *k*, projects at right angles from the impelling spring *h*, so as to intercept the pendulum-rod in its vibration, and at this place a small screw is put through the pendulum-rod *l*, the point of which moves the impelling spring back: a small pin is fixed to the frame, in a line between the point of suspension of the pendulum, and the centre of the swing-wheel, against which the impelling spring stops when at liberty.

"Supposing the pendulum to be vibrating backwards and forwards, and the wheel locked as in the figure, the pendulum swinging from *m* to *n*, the impelling spring *h* follows by its elasticity, until the pendulum *l* arrives at its perpendicular (or lowest point of its arc); at this period the impelling spring comes to rest against the end of the arc *e*, which it pushes back, so as to release the tooth of the wheel from the detent-spring *g*; the wheel now moves round a very small space before it meets the end of the impelling spring *h*, and is stopped thereby; in the mean time the pendulum continues its motion the extent of its vibration towards *n*, when it returns, and arriving at the perpendicular, it meets the impelling spring *h*, and carries it along with it, until the tooth of the wheel which rests against it escapes from the end of it, and another tooth of the wheel comes to rest against the spring-detent *g*. The succeeding vibration of the pendulum repeats the same operation." This is the whole account, from which the reader is induced to believe that the pendulum, and impelling spring *h*, act and re-act on each other *ad infinitum*, without any aid from the maintaining power through the medium of the wheel, which is never said to raise, or otherwise to move the impelling (or remontoir) pallet, in order that it may, in its turn, impel the pendulum by its acquired force. Again, it is said, the impelling spring unlocks the detent *g* when it arrives at the perpendicular, or nearly, if not quite, at the point of its quiescence, where it has *no force*, and from that point, not

REMONTOIR.

the wheel, but the pendulum unbends it into a state of tension, to resume its operation; that is, the pendulum raises the spring, that the spring may drive the pendulum back again; and thus the vibrations are maintained without the aid, and consequently without the necessity, of either a maintaining power or train; and what is equally extraordinary, the impelling spring locks the wheel by its *ressistance*, near the perpendicular line (within the space of one tooth), where it has almost the smallest force, or nearly the same small force that it has when it *unlocks* the *detent*. According to this account, even supposing the action of the wheel on the remontoir pallet to be *omitted*, the pendulum is under the influence of the impelling pallet during nearly the whole of one excursion, and free from it in the other. The model, however, is said to be preserved in the society's room, and will explain itself.

G. Prior's improved.—Mr. George Prior, jun. again presents an improved remontoir escapement for a clock to the society we have repeatedly had occasion to name in this article, in the year 1811 (vol. xxix.), and again receives a reward at their hands, of twenty guineas, for his improvement. The description given of this escapement, and of its action, is sufficiently clear, and the alteration made in the construction is in many respects an improvement, though we shall take occasion to shew, in our remarks on it, that it is still liable to objections. In the plate last referred to, *fig. 8.* contains the original *fig. 1.*, which will explain the account with sufficient precision. “The swing-wheel A,” says the author, “has thirty teeth cut in its periphery, and is constantly urged forwards by the maintaining power; C, D, are two spring-detents, catching the teeth of the wheel alternately; these are, at the proper intervals, unlocked by the parts marked 2 and 3 upon the pendulum-rod H, intercepting small pins *a, b*, projecting from the detents, as it vibrates towards the one or the other; E is the renovating or remontoir-spring, fixed to the same stud, F, as the detents; it is wound up by the highest tooth of the wheel, its position, when unwound, being shewn by the perpendicular dotted line. This being the case, suppose a tooth of the wheel caught by the detent D, which prevents the wheel from moving any further, and keeps the renovating spring from escaping off the point of the tooth; in this position the pendulum is quite detached from the wheel: now if the pendulum be caused to vibrate towards G, the part of it marked 2 comes against the pin *b*, projecting from the renovating spring E, and pushes this spring from the point of the wheel's tooth; on vibrating a little further, it removes the detent D, which detained the wheel, by the part 3 striking the pin *a*, which projects from the detent; the maintaining power of the clock makes the wheel, thus unlocked, to advance, until it is detained by a tooth resting upon the end of the detent C, on the opposite side; by this means the renovating spring will be clear of the tooth of the wheel as it returns with the pendulum, and gives it an impulse by its pin *b* pressing against the part 2 of the pendulum, until the spring comes to the position shewn by the dotted line, in which position it is unwound, and rests against a pin fixed in the cross-bar of the plate; the pendulum continues vibrating towards I, nearly to the extent of its vibration, when the part 1 meets the pin in the detent C, and removes it from the wheel and unlocks it; the maintaining power now carries it forward, pushing the renovating spring E before it, until another tooth is caught by the detent D, which detains the wheel in the position first described.” Agreeably to this description, the pendulum is opposed in its ascent, and accelerated in its descent, in one of its excursions from the centre, or perpendicular line, by both the impelling spring

E, and detent D, after it is unlocked, though not the whole distance; but is alternately accelerated and retarded in the other excursion by the detent C alone, and only after the unlocking; these unequal checks, given at different parts of the arc of vibration, we apprehend, are by no means favourable to the natural isochronism of the pendulum.

Hardy's.—Mr. Hardy, chronometer-maker, of Coppice-row, Clerkenwell, London, whose ingenious improvements in clock and watch-making have placed him high in public estimation, on contemplating Mr. C. Haley's failure in the locking of his remontoir detent, contrived a remedy which fully answers its purpose, and which, on that account, merits our particular notice.

Fig. 7. of *Plate XLI.* of *Horology*, represents the plan of Hardy's new remontoir escapement, which, though it appears to differ considerably in construction from Haley's, yet resembles it so much in its action, as well as principle, that we will put the same letters of reference to the same corresponding parts, in order that the reader who has perused our description of Haley's remontoir with attention, may the more clearly comprehend our description of Hardy's, and perceive in what the improvement consists. As in Haley's construction, T T represents the balance, or rather the place of the balance not seen; E the escapement, or balance-wheel; P the pivot of the verge; S the balance-spring, suspended as usual; K the impelled pallet; I the unlocking pallet of the remontoir; N the remontoir detent, or locking pallet, on the same axis with *a*, the arm of the slender or unlocking spring, which lies parallel with it; *n* the cock, taking the pivot of the remontoir detent's arbor, and also the upper end of its spiral spring; *c* the head of the banking screw, and *i* its stud; H the cock that takes the pivot of the remontoir, or cylindrical spring at W, and also one end of the said spring, represented by the small circle at R; L is the impelling lever or pallet, for giving motion to the pallet K of the balance; M is a lever, instead of the notch in Haley's large circular pallet, by means of which the wheel winds up the spring R of the remontoir; O is a lever, in place of the small ruby unlocking pallet of Haley, fixed to the snail; *d* is the spring-detent of the wheel, and *s* its ruby, or sapphire pallet, on which the wheel is locked, *f* and *g* being the banking screw and its stud, and *y* the place where it is fixed by a screw on the potance plate; and lastly, the sectoral piece Q, in which the improvement chiefly consists, is the addition introduced for rendering the locking of the remontoir-spring, when wound up, both certain and secure. The acting faces of the pallets *s, M, K, N*, and of the circular portion of Q, are of ruby, or other precious stone nicely polished, and are properly shaped for their respective offices. From this description of the mechanism before us, it will be perceived that the double spring *a*, and the detent with a claw pallet at N, are both fast to the arbor of the spiral spring, which gently presses the detent at all times down upon the sectoral piece Q, thereby preventing its being thrown back from its position for locking, as was the case with Haley's remontoir detent. It will also be seen that the arbor W, of the remontoir-spring R, has the said sectoral piece, the impelling lever L, the lever M impelled by the wheel, and the discharging lever O, all fast to it at different heights, the two first being above, and the two last below, so that when one of these four pieces is moved out of its first situation by any external force, they all move together, as do also the remontoir detent N and its spring *a* on their common arbor, and as do likewise the pallets K and I on the verge of the balance. These particulars being understood, and that levers in Hardy's construction are used

used for pallets in several instances, we may proceed to explain the action of the different parts, and to shew how they produce the desired effects of producing equable impulses on the balance at all times, and of effecting certain and secure locking of the remontoir-spring. In the figure before us, tooth 1 of the wheel has just proceeded far enough, by the action of the main-spring and train, to wind up the remontoir-spring, and its detent N, urged by its own spiral spring against the curved face of the sectoral piece, after sliding smoothly along it, has locked it; that is, by opposing it at right angles, prevents its return, which would take place when the wheel leaves the arm M, or, which is the same thing, when the remontoir-spring, on the same arbor with this arm, is wound up. The balance is now supposed to have commenced its motion, carrying the pallets K and I outwards from the wheel, but the small pallet I has not yet arrived at the slender spring of the remontoir detent, though it is approaching it; the slender spring, however, soon yields to the outward impulse of this small pallet, without disturbing its arm or the detent N, therefore the remontoir-spring remains locked: at the return of the balance, which takes place when its spring is wound up, the said little pallet I displaces not only the slender spring but its arm also, which lies next towards the wheel, the one not being liable to move in this inward direction without the other; the consequence is, that the detent N is now lifted by its connection with the arm of the slender spring, and at that instant the remontoir-spring, being wound up, and at liberty to act, throws back the sectoral piece Q nearly its whole breadth, but not quite, for the claw of the detent in question rests on the curve of the sector during the motion we have described, till the unlocking lever O strikes the end of the single detent-spring d, and forces the ruby pallet s out of the wheel, which wheel instantaneously resumes its motion from the train, and meeting with lever M winds up the remontoir-spring a second time; in the mean time the impelling lever L has given its impulse to the pallet or lever K, and consequently to the balance, which has thus had its momentum increased; and on its returning vibration exactly the same process is repeated. Thus the force of the maintaining power is expended in winding up at each alternate oscillation the remontoir-spring, which spring, so reinforced, impels the balance in its turn by quantities of force that are always the same, whatever may be the irregularities of the force transmitted through the train that winds up the remontoir-spring; therefore, properly speaking, the remontoir-spring is the maintaining power that restores, at each alternate oscillation, the loss of momentum that the balance has experienced from the resistance of the air, and friction of the parts in action. This escapement is, notwithstanding, of the detached kind, seeing the balance performs the greatest part of its oscillations without any connection of even the auxiliary force derived at intervals from the remontoir-spring; and a chronometer of this construction, made by Hardy for his royal highness the duke of Sussex, answers the maker's most sanguine expectation, and will probably become a model for other makers when its merit is proved, and made public. The same artist has made several experiments on the same principle, with this difference, that the remontoir-spring is retained by the lever resting on the tooth of the wheel, in place of being locked by the sectoral piece, as in the one before us.

Besides the preceding escapement, Hardy invented one for the astronomical clock he made for the Royal Observatory at Greenwich, which at first sight appears to resemble Mañey's and Prior's improved one, with spring pallets, but on close examination we discovered that it has the fol-

lowing desirable properties peculiar to itself: 1st, it gives the impulse not only from remontoir-springs, but strikes and unlocks the two separate detents alternately, at the instant when the pendulum has the *greatest velocity*; and, 2dly, the accelerating and retarding power imparted to the pendulum co-operates with the force of gravity, thereby deranging the natural law of gravity as little as possible. We feel not at liberty to enter more minutely into the description of this escapement, because we understand its inventor proposes giving an account of his machine himself, to be read before the Royal Society, as constituting the companion to Troughton's transit circle, already described by the astronomer royal. We have permission, however, to subjoin the rate of the clock in question for three quarters of a year, as taken at the Royal Observatory, which will afford the best proof of its pretensions to public notice. We have further to add, that the inventor has applied the same principle of movement to a chronometer of a large size, in which the balance has two metallic rods to adjust it for temperature, in place of the metal being fluxed on the rim of the balance, as is common. See COMPENSATION.

Trial of Mr. Hardy's clock at the Royal Observatory at Greenwich in the year 1811.

	Daily Rate.	Mean of Thermometer.
April 12 to May 13 - - -	0.86	61
May 13 to June 9 - - -	0.74	63
June 17 to July 12 - - -	0.74	64
July 18 to August 17 - - -	0.83	68
August 17 to September 14 -	0.77	65
September 14 to October 4 -	0.61	60
October 17 to November 17 -	0.60	51
November 17 to December 10 -	0.50	46
December 10 to December 30 -	0.47	39

From the above stated authentic document it appears, that for the nine months of trial, and in opposite extremes of temperature, the daily rate never varied quite *four-tenths* of a second; and when the quantity of mercury proper for the compensation of the pendulum is exactly ascertained, it may be expected that the performance will be still more accurate; seeing that the deviation in the rate depends evidently on the change of temperature, and not on the escapement.

REMORA, in *Natural History*, the *sucking-fish*; a little fish, resembling a herring, called by the Greeks *echeneis*, famous for sticking to the sides of ships. It belongs to the genus of *echeneis* and class of *thoracici* in the Linnæan system.

Its characters, according to Artedi and Linnæus, are these: the branchiostege membrane on each side contains about ten bones; the head is thick, depressed, naked, and marked on the upper side with transverse rough striæ; the body is oblong, roundish, and naked, but somewhat compressed; the back-fin is oblong, and placed very far toward the tail; its under jaw is longer than its upper; it has a great number of teeth in both jaws; the colour of its body is hoary, and it has seven fins; two pectoral ones, two ventral ones placed farther from the snout than the pectoral ones, one at the anus, one on the back, and one at the tail; the striæ of the head are from eighteen to twenty-four in number, they are rough and transverse, but are divided as it were into two series by a middle longitudinal line. By means of these striæ or ridges the fish can fix itself to any animal

animal or other substance, and has often been found adhering to the sides of ships and the bodies of sharks, &c.

Linnaeus enumerates two species of the echeneis; the remora and neurates: the former has a forked tail, and eighteen striæ on the head; the latter has an entire tail, which is longer than that of the former, twenty-four striæ, a larger body, and sharper fins. They are both inhabitants of the Indian ocean. The remora is much talked of by the ancients, who, as we find from Pliny, lib. ix. cap. 25. lib. xxxi. cap. 31. unanimously believed it had the force to stop a vessel in full sail, or a whale in swimming; and hence called it *remora*, a *remorando*. (See Ælian's *Hist. de Animal.* lib. ii. cap. 17. Plutarch. *Sympos.* lib. ii.) But Mr. Catesby observes, that even several of those fishes together can do no more than shells or corals, and other foulnesses of the same bulk, which make a ship sail somewhat the slower. And in the same manner only they may be some small hindrance to a whale. The author last mentioned assures us he has taken five of them off the body of a shark. Vide *Phil. Trans.* N^o 438. p. 113.

REMORA, among *Surgeons*, is also an instrument used for setting broken bones.

REMORA *Mutiani*, in *Natural History*, a name given by some to the genus of shells called *concha venerea*, and *porcellana*. See *PORCELAIN Shell*.

REMOTION, REMOTIO, in *Rhetoric*, the same with what is otherwise called *metastasis*.

REMOVAL of the *Poor*. See *POOR*.

REMOVELLE, in *Geography*, a town of France, in the department of the Vosges; 5 miles E. of Neufchateau.

REMOVING *Obstructions to Tillage*, the means of removing stones and any other substances that may be in the way of the plough.

The operations which are to be performed in these intentions are of several different kinds, as the removing of various forts and states of stony matters, both from above and below the surface of the lands; the eradicating and destroying different kinds of woody materials of the tree, root, and plant forts, the taking away of the superabundant wetness; the destruction of many aquatic vegetables, and some others. See *LAND, STONE, TILLAGE, and WOOD*.

REMOULIN, in the *Manege*, is used to denote a star upon a horse's forehead.

REMOULINS, in *Geography*, a town of France, in the department of the Gard, and chief place of a canton, in the district of Uzès; 7 miles S.E. of Uzès. The place contains 905, and the canton 4758 inhabitants, on a territory of 135 kilometres, in 8 communes.

REMOUNT, in *War*. To *remount the cavalry*, or *dragoons*, is to furnish them with fresh horses, in lieu of such as have been killed or disabled in the service.

REMPHAN, in *Antiquity*, the Egyptian name for the planet Saturn. Some think that remphan was the moon, others Mercury and Mars, and others the sun. See *CHIUN*.

REMPLY, in *Heraldry*, something *filled up*. The term is chiefly used to denote, that the chief is quite filled up with a square piece of another colour, leaving only a borderure of the proper colour of the chief about the said piece.

REMPORETTY, in *Geography*, a town of Hindoostan; 30 miles N. E. of Travancore.

REMS, a river of Wurtemberg, which runs into the Neckar, 4 miles N.W. of Waiblingen.

REMSA, or REMISSAM, a town of Saxony, in the lordship of Schonburg; 2 miles N.N.E. of Glauchau.

REMSCHIEDT, a town of the duchy of Berg; 2 miles S.W. of Lennep.

REMSEN, a township of America, in Oseida county, New York, E. of Leyden and adjoining it.

REMUNGOL, a town of France, in the department of the Morbihan; 7 miles S. of Pontivy.

REMURIA, among the Romans, a festival instituted in honour of Remus by his brother Romulus. See *LEMURIA*.

REMUZAL, in *Geography*, a town of France, in the department of the Drôme, and chief place of a canton, in the district of Nyons; 6 miles N.E. of Nyons. The place contains 514, and the canton 3724 inhabitants, on a territory of 272½ kilometres, in 17 communes.

REMY, a town of France, in the department of the Oise; 6 miles N. of Clermont.

REN, a town of Russia, in the government of Novgorod; 16 miles S.E. of Ustiuzna.

RENAISON, a town of France, in the department of the Rhône and Loire; 6 miles W. of Roanne.

RENAIX, a town of France, in the department of the Scheldt, and chief place of a canton, in the district of Audenaerde. The place contains 9499, and the canton 14,683 inhabitants, on a territory of 70 kilometres, in 6 communes.

RENALIS, RENAL, in *Anatomy*, an epithet applied to the parts belonging to the kidney; as to the artery and vein of the organ, also called *emulgent*, of which the former comes from the aorta, the latter joins the inferior vena cava; see *ARTERY* and *VEIN*: to the plexus of nerves derived principally from the ganglia of the great sympathetic; see *NERVE*: and to the small bodies placed above the kidneys, called the *renal capsules*. See also *KIDNEY*.

RENALIS *Lapis*, in *Natural History*, the name given by many authors to a sort of siderochitum, or cruftated ferruginous body of that kind, containing a nucleus of a different matter from that of the crufts. It is found about Prague, and in some other places, lying near the surface in strata of a yellow clay. Its usual bigness is that of a ripe peach, and its crufts are of a dusky ferruginous brown colour: and its internal nucleus of a pale yellowish-green, composed of a marley earth, and usually of a kidney-like shape, whence its name.

RENASSAU, in *Geography*, a town of Hindoostan, in Dowlatabad; 114 miles N.W. of Hydrabad. N. lat. 18° 30'. E. long. 79° 10'.

RENATHIA, a town of Asiatic Turkey, in Carmania; 10 miles S.W. of Satalia.

RENAU D'ELISAGARAY, BERNARD, in *Biography*, a distinguished engineer and naval architect, was born in the province of Bearn, in the year 1652. He was at an early age instructed in the mathematical sciences, and was observed not to read a great deal, but to think most profoundly, and as he advanced in years, he was capable of thinking upon the most abstruse subjects, as well in the midst of company, as in the closet. One of the first books that attracted his attention was Malebranche's "Recherche de la Verité," and, it is said, it made such an impression upon him, that nothing could efface it through the whole of life. It gave him a full conviction of the truths of religion, and preserved his morals pure and uncorrupted. In 1679 he was placed with the count de Vermandois, admiral of France, as his instructor in naval affairs. When, by the royal command, conferences were held to determine upon a plan for bringing to perfection the construction of vessels, Renau was called upon for his opinion; and at length the systems of Du Quesne and that of Renau were alone left for consideration, and to the honour of Renau, then young and almost unknown, his plan was adopted, and he himself was sent to Brest and the other ports to put it in execution.

In 1680, the Algerines having declared war against France, Renau proposed the bombardment of Algiers, for which purpose he conceived the idea of bomb-vessels, which were as yet unknown. This was at first regarded as visionary; but reliance being placed on his talents, he was permitted to make the trial, and he brought five of these vessels before the town, where, under the command of Du Quesne, the bombardment was executed with complete success. In 1684 he was employed, as engineer, at the bombardment of Genoa; from this place he went to join Vauban, who was fortifying the frontiers of Flanders and Germany, and he contracted an intimate friendship with that great man. In 1688 he accompanied Vauban to the siege of Philipsburg, and afterwards conducted, or was present, at some other sieges; yet in the midst of these active services he found leisure to attend to his studies, and published in 1689 his "Theorie de la Manœuvre des Vaisseaux:" some of the propositions in this work were contested by the celebrated Huygens. In this same year he endeavoured to prove, by argument, that the navy of France might be rendered capable of making head against that of England and Holland united, and his observation produced such an effect upon the government, that an order was made to change all the 50 and 60-gun vessels, on the stocks, into ships of a higher rate. About the same time he invented a new series of naval evolutions, signals, and orders of battle. His merits were well understood by the government, who rewarded him with a pension, and considerable rank in the service. He was now sent to Brett for the purpose of instructing the naval officers in his newly invented evolutions, &c. He met with an opposition, which is not uncommon in endeavouring to change old established customs. Of his opponents, two of the most distinguished were put under arrest and broke, though he did his utmost to prevent the punishment being carried to that extremity. He afterwards served under Vauban at the siege of Namur, from thence he repaired to St. Malo after the battle of La Hogue, to save the relics of the French fleet which had taken shelter there. Having constructed a vessel of 54 guns upon his own plan, Renau put to sea with the view of intercepting two rich English East Indiamen, one of which he captured after a desperate engagement. Among the booty were some packets of diamonds, which he thought of too great value to be claimed by himself, though the naval customs would have justified him in it, and he carried them to the king, who accepted the prize, and remunerated the captor with an annuity. When Philip V. succeeded to the crown of Spain, he sent to his grandfather, Lewis XIV., to request that he might have Renau to direct his engineers in fortifying his most important towns. He found means to render the crown of Spain the most important services, and was, in 1704, employed in the siege of Gibraltar, which, it has been assumed by the French biographer, was about to surrender, when it was relieved by the English fleet. To the disgrace of the court of Spain, whose interests he had effectually promoted, and in whose cause he had expended his own property, he was suffered to return to France with a single pistole in his pocket, though his Catholic majesty had given him the title of lieutenant-general of the armies of Spain. The high reputation which Renau had acquired as an engineer, caused the grand-master of Malta to request that he might be sent to that island on an alarm of an invasion, which was readily granted. Soon after this Lewis XIV. died, and the duke of Orleans succeeded to the regency, who appointed Renau to be counsellor of the marine council, and grand-croix of St. Louis. He died of a dropsy in 1719, and his death

was, like that of La Trappe, in ardent aspirations after another life: "What a difference," he exclaimed, "from one moment to the following! I am going to pass in an instant from the thickest darkness to perfect light." He had been twenty years an honorary member of the Academy of Sciences, and was among the first after that class was instituted.

RENAUDOT, EUSEBIUS, a learned writer on the ecclesiastical history and antiquities of the Eastern church, was born at Paris in 1646. He was educated at the Jesuits' college, and entered the congregation of the oratory when he was about 19 years of age, though he had no intention of entering into holy orders, or to the taking any ecclesiastical degree. He was particularly attached to the study of the oriental languages, in the knowledge of which he far excelled almost all his contemporaries; and he applied with success to the study of so many other tongues, that he was sufficiently master of seventeen different languages, to be able to speak the greater number of them with facility. He became well known at court, where his genius, his talents, and his politeness, made him much esteemed and admired. Here he was noticed by M. Colbert, who was desirous of establishing printing-presses for the oriental languages at Paris, and consulted Renaudot upon the subject, as a person who might ably contribute to render such an establishment useful to the state as well as the church. To engage his assistance, he promised him the reversion of the post of keeper of the king's library; but the minister died before the place became vacant. He received a similar promise from the archbishop of Rheims, and was again disappointed. He was, however, employed by the king in various confidential concerns of great importance relating to the affairs of Rome, England, Spain, &c. So much was his time occupied by these engagements, that he almost entirely discontinued his favourite studies. In the year 1689 he was received into the French Academy, and in 1692 into the Academy of Inscriptions and Belles Lettres. He found a patron in the cardinal de Noailles, archbishop of Paris, whom he accompanied to Rome in the year 1700, and into the couclave which elected Clement XI. to the papal dignity. While he remained in that city, the collections of the Vatican furnished him with new matter relating to the oriental churches, and revived an intention, which he had long before encouraged, of preparing for publication some pieces which serve to illustrate their history and opinions. In this design he was assisted by the new pope, who persuaded him to remain in Rome several months after the departure of cardinal de Noailles. His holiness would gladly have conferred upon him some valuable benefices, but he refused to accept of any thing beyond a small priory. The abbé Renaudot afterwards went to Florence, where he met with most flattering reception from the grand duke, who assigned him apartments in his own palace, loaded him with presents, and on his departure directed that he should be conveyed on board one of his own vessels to Marseilles. At Florence, likewise, he was made a member of the Academy de la Crusca. Soon after his return from France, he was roused by an attack upon father Nicole's "Perpetuity of the Faith of the Catholic Church respecting the Eucharist;" and in 1708 he published "A Defence of the Perpetuity of the Faith against the Calumnies, &c." He afterwards entered more fully into the subject which he defended, and displayed all his erudition and ingenuity in endeavouring to shew the conformity between the doctrine of the Greeks, and all the oriental Christians, with that of the Latin church. What he wrote upon the subject extended to two vols. 4to. which were published in 1711 and 1713, by way

of supplement to father Nicole's work. During the regency of the duke of Orleans he made frequent efforts to obtain his encouragement of the plan for establishing printing-presses for the oriental tongues, and was promised, but never obtained effectual support. The latter years of his life he spent in completing numerous very learned and important publications, among which may be mentioned, "Historia Patriarcharum Alexandrinorum Jacobitarum:" "Liturgiæ Orientalium Collectio," in 2 vols., accompanied with very learned dissertations: "Ancient Accounts of India and China, by two Mahometan Travellers in the 9th Century, translated from the Arabic." Renaudot died in the year 1720, at the age of 74 years, greatly regretted by the literati of that age, to whom he was a communicative and most agreeable companion, and lamented by the poor, to whose relief he had dedicated a large portion of his income. Moreri.

RENAY, or RONSE, in *Geography*, a town of France, in the department of the Jemappe, with a magnificent chateau; 7 miles S. of Oudenarde.

RENCHEN, a town of the duchy of Baden; 4 miles N.N.W. of Oberkirch.—Also, a river of Baden, which rises in the Orttau, and runs into the Rhine, 10 miles N. of Oberkirch.

RENCOUNTER, formed from the French, *rencontre*, *meeting*, in the *Military Art*, the encounter of two little bodies or parties of forces.

In which sense, rencounter is used in opposition to a pitched battle.

RENCOUNTER, in single combats, is used by way of contradistinction to duel.

When two persons fall out, and fight on the spot, without having premeditated the combat, it is called a rencounter.

RENCOUNTRE, or RENCONTRE, in *Heraldry*, is applied to animals when they shew the head in front, with both eyes, &c. or when the face stands right forward, as if they came to meet the person before them.

Indeed, in deer, this is called *masacre*; and, in the leopard, it is the natural situation. He bears fable, in rencountre, a golden fleece.

RENDE, in *Geography*, a town of Naples, in Calabria Citra; 5 miles N.N.W. of Cosenza.

RENDER, in *Law*, a term used in levying a fine. A fine with render, is that by which something is rendered back again by the cognizee to the cognizor.

The lawyers also say, there are certain things in a manor, which lie in *prendre*, *i. e.* which may be taken by the lord, or his officers, when they please, without the tenant's leave; and others which lie in *render*, that is, must be rendered or answered by the tenant, as rents, reliefs, heriots, and other services. See *PRENDER*.

Some service consists in seizure, some in render.

RENDERING, in *Building*. See *PARGETING*.

RENDERING, in *Sea Language*, is generally understood to be the effect of yielding or giving way, without resistance, to the efforts of some mechanical power. It is usually expressed of a complicated tackle, lanyard or lashing, when the effect of the power applied is communicated with facility to all the parts, without being interrupted in its passage. It is therefore used in contradistinction to jamming.

RENDEZVOUS, or RENDEVOUS, a place appointed to meet in, at a certain day and hour.

The word is French, and is found so commodious, that most nations use it in its purity, for want of a word of equal import in their respective languages.

Thus, in a military sense, the rendezvous is the place appointed.

pointed by the general, where all the troops that compose the army are to meet at the appointed time, in case of an alarm; and the regiments have their particular rendezvous, called their quarters of assembly.

In a naval sense, it denotes the port or place of destination, where the several ships of a fleet, or squadron, are appointed to rejoin the whole, in case of a separation, occasioned by tempestuous weather, or other unforeseen accident.

RENDEZVOUS Bay, in *Geography*, a bay on the S. coast of Antigua, W. of Falmouth harbour.

RENDEZVOUS, *Island of*, an island, or rock, in the southern Indian ocean, discovered in 1773 by M. de Kerguelen, near the N. coast of Kerguelen's land, and called by captain Cook "Bligh's Night-cap."

RENDEZVOUS Key, a small island in the bay of Honduras, near the coast of Mexico. N. lat. 16° 59'. W. long. 88° 40'.

RENDS, in a *Ship*, are the same as the seams between her planks.

RENDSBORG, in *Geography*, a town of Germany, in the duchy of Holstein, seated on a canal which communicates with the Baltic, on the borders of Sleswick, supposed to be one of the strongest towns in the Danish dominions, and generally well garrisoned. The number of inhabitants is about 3600; 15 miles W. of Kiel. N. lat. 54° 22'. E. 9° 52'.

RENE', a town of France, in the department of the Sarthe; 15 miles N. of Le Mans.

RENEALMIA, in *Botany*, a new genus of Mr. Brown's, has lately received that name from him, in just commemoration of Paul Renealmus, or Renaulme, a physician at Blois, who published, in 1611, a thin quarto volume at Paris, entitled *Specimen Historiæ Plantarum*, with expressive, but stiff, and not neatly finished, engravings in copper, in which each plant is distinguished by an appropriate Greek name, mostly of the author's invention. Mr. Brown observes, that this author was the first who paid attention to the differences in the number, situation, and proportion of the stamens. Linnæus, in his own copy of the work, has expressed a well-founded surprize, at its being never quoted by the Bauhins. Plumier was the author of the first *Renealmia*, now sunk in the Linnæan *Tillandsia*. Linnæus, or his son, dedicated a monandrous genus, in the *Supplementum Plantarum*, to the memory of this meritorious botanist; but it proved not distinct from a more generally-received genus, of the same date, *Alpinia*. We with the present *Renealmia* may be found sufficiently different from *Sifyrinchium*, to which its species were originally referred by its learned author.—Brown Prodr. Nov. Holl. v. 1. addend. (*Sifyrinchium*; *ibid.* 304.)—Class and order, *Monadelphia Triandria*. Nat. Ord. *Ensatæ*, Linn. *Irideæ*, Juss. Brown.

Ell. Ch. Calyx none. Petals six, regular; three inner ones largest, contracted at the base. Style one. Stigmas three, thread-shaped, involute, acute. Capsule inferior, obovate, of three cells. Seeds angular.

The species are herbaceous, smooth, inhabitants of woods. Roots fibrous, sometimes tuberous. Leaves grassy, lax, ribbed. Stem roundish, sometimes divided. Flowers in alternate umbellate bunches, with short permanent sheaths. Corolla regular, white, spreading, soon falling off; the outer petals generally greenish at the back; the inner often furnished with claws. Filaments either combined below, or distinct; their upper part spreading. Capsule membranous. Seeds in two rows, black.

1. *R. paniculata*. Panicked Renealmia. Brown n. 1.—Stem panicked. Leaves ribbed; roughish at the edge. Outer petals

petals linear-lanceolate; inner scarcely twice as large, obovate-oblong. Filaments united half way up.—Gathered by Mr. Brown, near Port Jackson, New South Wales. The leaves are all from ten to eighteen inches long, and for the most part rough-edged.

2. *R. grandiflora*. Large-flowered Renealmia. Brown, under the former.—Stem panicled. Leaves ribbed; roughish at the edge. Inner petals four times as large as the outer. Filaments united half way up.—Gathered by the Rt. Hon. Sir Joseph Banks, in New Zealand. Akin to the former, but differing in the proportion of its inner petals, which are four or five times the size of the outer.

3. *R. pulchella*. Elegant Small Renealmia. Brown n. 2.—Stem nearly simple. Leaves with smooth edges. Outer petals oval-oblong; inner obovate, with short claws. Filaments distinct.—Gathered by Mr. Brown near Port Jackson. The leaves are only three or four inches long.

RENÉE DE FRANCE, in *Biography*, duchess of Ferrara, born at Blois in 1510, was daughter of Lewis XII. and Anne of Brittany. She was affianced, when very young, to Charles of Austria, afterwards emperor, and some years after was sought in marriage by Henry VIII. of England, but neither of these matches took place, and Francis I. gave her to Hercules II. of Este, duke of Ferrara. This princess is celebrated for her talents: she had a great capacity, and an insatiable thirst for knowledge, and her studies were not limited to history, the languages, and mathematics, but embraced various other topics, especially astrology and theology. The religious controversies of the time greatly interested her, and she became zealously attached to the tenets of the reformers; her court at Ferrara became the refuge of all who were suspected of heresy; and her conduct gave so much offence to the court of France, that Henry II. sent a doctor to the duke with the following instructions: "If the duchess persist in her errors, she must be separated from all conversation: her children must be taken from her, and all her domestics who are suspected of heresy, and who are to be prosecuted; with regard to the princess herself, the king refers to the prudence of her husband to proceed against her as he shall judge proper, avoiding, nevertheless, what might occasion too much scandal." After the death of the duke, in the year 1559, this princess returned to France, and resided at her castle of Montargis. In the religious wars the duke of Guise summoned her to deliver up some partisans who had taken shelter with her, she replied, "I will never deliver up those who look to me for protection; and if you attack the castle, I will be the first to appear in the breach, to see if you will have the audacity to kill a king's daughter." She was, however, at length obliged, much against her will, to send away 460 persons, to whom she had afforded an asylum. She parted with them in tears, after providing for the expences of their journey. At the massacre of St. Bartholomew she was the means of saving the lives of a great number of Protestants. Her four children were taken successively from her, and brought into France, to be educated in the principles of the Catholic church. She died at Montargis, in the year 1575. Moreri.

RENEGADO REEF, in *Geography*, a rocky shoal in the bay of Honduras, near the coast of Mexico. N. lat. $16^{\circ} 16'$. W. long. $88^{\circ} 50'$.

RENEGATE, RENEGADO, a person who has apostatized, or renounced the Christian faith, to embrace some other religion, particularly Mahometanism.

They are the renegades who prove the most barbarous to the Christians when they fall into their hands. The renegade is thus called, *quasi re-negat Christum*.—Hoveden men-

tions this in the year 1192, under the name of *renier*, from the French, *renier*, to deny again.

RENDELE, in *Geography*, a river of France, which runs into the Seine near Rouen.

RENDLING CURD, in *Rural Economy*, a term used provincially to signify the broken curd in cheese-making. See CHEESE and DAIRYING.

RENES, in *Anatomy*, the Latin name for the kidneys. See KIDNEY.

RENES *Succenturiati*, the two small bodies, of which one is placed above each kidney. The literal translation of the expression, *reserve kidneys*, seems to indicate a notion, entirely unwarranted by our knowledge of their organisation and functions, that they might supply the place of the kidneys if they failed in their office. These bodies are also called capsule renales or atrabiliaræ, and glandulæ suprarenales. They are described in the article KIDNEY.

RENESBONA, in *Geography*, a river of America, which runs into lake Erie, N. lat. $41^{\circ} 47'$. W. long. $81^{\circ} 55'$.

RENETTE, in the *Manege*, is an instrument of polished steel, with which they sound a prick in a horse's foot.

RENEWING of Leaves and Lives. See REVERSION, ANNUITY, POLITICAL Arithmetic, &c.

RENFORCER, Fr., in *Musick*, to reinforce, to pass from soft to loud, from loud to very loud, not all at once, but by degrees, swelling and augmenting the sound, whether a single note sustained, or a series of notes, till the order to reinforce the note or passage is fulfilled, and then return to the common degree of force.

RENFREW, in *Geography*, a royal borough-town in the county of Renfrew, Scotland, is situated near the south bank of the river Clyde, at the distance of six miles from Glasgow, and 49 miles W. by S. from Edinburgh. Though much inferior in magnitude and population to Paisley, it is the head-town, or capital of the county. This distinction it derives from its superior claims to antiquity, and from the circumstance of its being incorporated under a royal charter, originally granted by king Robert II., who had a palace in the immediate vicinity. In virtue of that deed it is governed by a provost, two baillies, and sixteen counsellors. In former times it sent one representative to the parliament of Scotland, and is now a contributory royal borough with Rutherglen in returning a member to the British legislature. About 200 years ago the Clyde passed close to the town, but the river afterwards deserted its ancient course, which has been converted into a canal communicating with its present channel. By this canal vessels of 200 tons burthen are enabled to reach the town in spring tides; but notwithstanding the advantage of that conveyance, the trade of Renfrew is very inconsiderable; owing, as Mr. Forsyth justly remarks, "to the pernicious effects of borough politics, in withdrawing men from industrious habits and pursuits." A small manufacture of thread, and some soap and candle works, on a confined scale, constitute the chief support of the town; but many of the lower orders are likewise employed in weaving for the manufacturers of Paisley and Glasgow. With respect to buildings, Renfrew consists chiefly of one principal street, about half a mile in length, with several lanes diverging from it. The houses are wholly constructed of stone, but are extremely irregular as to size, form, and position. The public buildings are the church, which is parochial, the town-hall, and a grammar-school. The last is under the patronage of the town-council, and is at present conducted with much ability. There is no regular market held here, but provisions of all kinds may always be obtained at a reasonable price. The fairs

fairs take place on the third Tuesday in May and July, the 29th of September, and the first Friday in December. A general post-office is established at Renfrew. The revenue of the corporation exceeds 500*l. per annum*, arising from the rents of lands, customs, a salmon fishery on the Clyde, and the profits of a public ferry over that river. This ferry is perhaps the object most worthy of notice of any connected with the town. There is a ferry-house on each side of the river, the property of the corporation; and a ferry-boat constructed in so convenient a manner, that a carriage, with a pair of horses harnessed, can be ferried over and delivered by one man in five minutes. This is accomplished by fixing, on both banks of the river, a rope which runs upon rollers at each end of the boat, and being pulled by the boatman puts it in motion. Renfrew, as the shire town, is the place where all county meetings are assembled, and where the county quarter sessions of the peace are held.

Renfrew parish extends between three and four miles in every direction. The whole is level, inclosed, and in a high state of cultivation. The soil is a rich loam, and the climate is peculiarly healthy, though subject to occasional heavy rains. The burgh lands consist of about a hundred acres. This parish is intersected by the great road between Glasgow and Greenock. Ecclesiastically considered, it is within the presbytery of Paisley, and the synod of Glasgow and Ayr. According to the parliamentary returns of 1811, the number of its houses is estimated at 344, and its inhabitants amount to 2305. Beauties of Scotland, 8vo. vol. iii. Carlisle's Topographical Dictionary of Scotland, 4to. 1813.

RENFREWSHIRE, a county in the south-western division of the kingdom of Scotland, is bounded on the east by Lanarkshire, on the west, north, and north-east by the river Clyde, and on the south-west by the hills of Ayrshire. This county is of small extent, and of irregular shape; and contains, according to the parliamentary returns of 1811, 8409 houses, and a population of 92,596 persons. In general, and especially along the northern parts of it, the surface of the ground is level; but there are nevertheless several ridges of hills within its boundaries, some of which, upon the borders of Ayrshire, are of considerable elevation. The hills of Balagich and of Dunware rise to the height of 1000 feet above the level of the sea; and the isolated hill, called the Craig of Neilston, to 820. This last is covered with fine grass to its very summit. Those adjoining to Ayrshire, however, are bleak and barren, but command very fine views. On the south and west sides, the fertile vale of Cunningham, which seems at a distance to be wholly covered with wood, stretches itself to the shore of the Clyde; while on the north and north-east are beheld the level parts of Renfrew and the city of Glasgow, with the lofty Ben-Lomond towering above the clouds, in the back ground.

The rivers and lakes of this county are not of very considerable consequence in relation to themselves, but by the industry of the inhabitants on their banks, they have been rendered of great importance and utility to society. Unlike the romantic waters of Ayrshire, adorned with wood and exciting interest by the vestiges of ancient magnificence which they every where display, the streams of this district are made subservient to the purposes of human industry. If they descend from a height, it is not to add to the charms of the surrounding scenery, but to give motion to extensive machinery, inclosed within immense piles of building, where hundreds of mortals toil in the service of luxury, or form the materials which are to furnish clothing to distant nations. Here, if a stream spreads abroad its waters, it is not to embellish a park, but to afford convenience to a bleach-field, or to serve a reservoir for the mills in case of drought. In

proportion as Glasgow is approached, every thing assumes an aspect of activity, of enterprise, of arts, and of industry. The principal streams are the White-Cart, the Black-Cart, and the Grif, which fall into the Clyde below Inchinnan bridge. The White-Cart, which generally receives, by way of eminence, the Cart, runs in a direction from south-east to north-west, nearly parallel with the Clyde. It takes its rise in the moors of East Kilbride, Lanarkshire, and is particularly celebrated in ancient record for its fine large pearls. These, however, have long disappeared; but the river is become a source of more certain and beneficial wealth by its utility to the manufacturing interests of the county. Above Paisley, which stands upon its banks, it winds its way through a variety of small hills capable of cultivation to their summits; sometimes disappearing altogether, and again spreading its waters abroad into the plain. Below the town it is navigable for small vessels, and is thus beneficial to commerce and trade by facilitating the conveyance of goods. The Black-Cart rises out of Castle-Semple loch, in the parish of Lochwinnoch. From that beautiful lake it descends northward, and receives in its course the waters of the Grif. This last stream has its source in the elevated territory above Largs, which looks down upon the angle formed by the frith of Clyde. After its union with the Black-Cart, these conjoined rivers flow into the White-Cart at Inchinnan bridge. The lakes in the county, besides that of Castle-Semple above mentioned, are Queenside loch, in Lochwinnoch parish, two lochs in Neilston parish, and various other smaller ones, all of them appropriated to useful purposes.

The mineralogy of this county, though not so important as that of some others in Scotland, is nevertheless deserving of attention. In the parishes of Eaglesham and Kilbarchan, the mineral called the osmund stone is frequently found. This remarkable stone is of various colours, and when newly quarried, is so soft that it may be cut with a chisel; but afterwards becomes much harder. It breaks in all directions with unequal and harsh surfaces, readily absorbs water, and if recently heated, the absorption is attended with a hissing noise. Acids do not affect it, nor is it rent or melted by a strong heat. Hence it is much used for paving ovens, furnaces, &c. When burnt, it assumes a darkish colour, and loses three *per cent.* of its weight, but afterwards regains it by absorption. Some of it is considerably porous, and almost semivitrified, in which case, when struck, it emits a clear and strong sound. It is found in large masses in the form of rocks, having the intervening spaces filled with siliceous or calcareous spar, and occasionally with zeolite, steatites, and barytes. This last mentioned substance is found in abundance at Balagich hill in the parish of Eaglesham, where are likewise two very noted mineral springs. But the chief field of minerals in Renfrewshire is that in the vicinity of Paisley, which extends on the one side into the parish of Kilbarchan, and on the other towards Glasgow. That part of it which is most singular is the coal at Quarreltown, which is undoubtedly one of the most extraordinary masses of that mineral hitherto discovered in the British dominions. Its thickness, measured at right angles, is fifty feet; and it consists of five layers or strata in contact with each other. In consequence of its enormous depth, it is wrought in different floors, in the mode practised in great open quarries. It is difficult to form a just conception of the manner in which this singular mass of coal lies. In a field of fifteen acres, it is found to dip in various directions. At least, conceiving a nearly circular area of these contents, the coal, from the north, the east, and south quarters of that circle, dips pretty uniformly towards the centre. This,

RENFREWSHIRE.

however, is in some measure interrupted by several hitches, at one of which the mass of coal is suddenly thrown up about fifty feet, at another above thirty. These hitches interrupt not only the direction, but the degree of the dip. On one side of the northern hitch, it is about one foot in three; on the other side, only one in six. Some years ago, this bed of coal having taken fire, the pillars gave way and the ground sunk, leaving the surface in a very rugged state. The difficulties thus produced, however, have been surmounted, and this mineral treasure restored to all its utility. The other coal-mines in the county of Renfrew, are those of Hawkstead, Cathcart, and Kilbarchan. The first has been wrought above 200 years. In the same neighbourhood, lime is quarried in great quantities, also in Cathcart parish. Iron-stone accompanies all the coal strata, but is more particularly abundant along the shores of the Clyde.

On the agriculture of Renfrewshire, it will be unnecessary to offer many remarks. Almost every portion of the county is inclosed and cultivated, but grass lands are far more predominant than arable fields. This arises from the great demand which exists for the products of the dairy, the garden, and the fold, in consequence of the vicinity of trading and manufacturing towns, and the vast importation of grain which takes place from other parts of the country, or from abroad. Here the farmers are more sensible than to object to a free commerce in that article; because they do not envy the inhabitants of less populous districts, who find no better employment for their lands than that of scourging them by endless crops of grain. One would imagine that the practice in this district alone ought to decide the principle of the corn laws. Here, free importation, so far from injuring the farmer, augments the value of the soil in every respect, simply by increasing the ratio of population.

The lands here differ according to their vicinity to the Clyde, or in the lower part of the county, according to their proximity to the waters of the Cart. In the parishes of East-Wood and the abbey of Paisley, the lands are beautifully interspersed with small rising hills, although the soil is generally of a thin clay. Here the farmers keep one half of their grounds in grass, which they consider as the most important crop. In the upper district of the county, which comprehends the parishes of Mearns, Eagleham, Neillston, Lochwinnoch, Kilbarchan, Erskine, and Kilmalcolm, the lands are peculiarly adapted for pasturing sheep, but none of them are so stocked, excepting some inclosures about gentlemen's seats, and a few parks in Neillston parish. The parish of Mearns is perhaps unequalled in Scotland for numerous small hills. The farmers here make large quantities of butter. The cows are small, of a brown and white colour, and are chiefly of the Ayrshire breed. Twelve of them afford, during the summer months, about sixty English gallons of milk daily. Towards the northern part of the county, in Kilmalcolm parish, the enclosures are generally formed of stones piled up to the height of four feet. The rotation of crops is three successive crops of oats, and six years of pasturage. Farm servants are usually unmarried, and live in the farmers' houses. The horses are of the best kind, and draw, in a single horse cart, from 17 cwt. to a ton. Farms throughout the whole county are on a small scale; few of them exceed seventy acres.

Renfrewshire contains one borough-town, Renfrew, and three large manufacturing and commercial towns; *viz.* Paisley, Greenock, and Port-Glasgow, all of which are noticed under their respective names. Here are likewise several populous and thriving villages, such as Pollockshaws, Bridge of Johnstone, and Lochwinnoch, which are chiefly inhabited by weavers, who derive employment from

the manufactories of Glasgow and Paisley. The principal manufactured products are thread, silk-gauze, and different kinds of cotton goods.

Various remains of antiquity are still visible in this county. At Paisley was a celebrated abbey for monks of the order of Clugni, the ruins of which are much admired. Here is also an old chapel, in the early pointed style, which is noted as the burial place of Margery Bruce, and several of the earls of Abercorn. In the parish of Kilbarchan, near Castle-Semple, is one of those monilrous masses of whinstone, believed to be a druidical altar. It is twelve feet in height, and sixty-seven feet in circumference; and is known by the name of Clochodrigstone, a corruption of the Gaelic, Cloch-a-Drugh, the Druid's stone. It is composed of the same sort of whinstone of which the neighbouring hills are formed, and has probably been hewn from an elevated rock to the eastward, on which is a farm-house, called also Clochodrig; but by what mechanism it was conveyed cannot, in the present application of the mechanical arts, be easily determined. It rests upon a narrow base; but the lower part of it has been covered with stones gathered from the land. At some distance are several large grey stones, supposed to have been part of a sacred circle surrounding the altar. The parish of Cathcart is noted for being the scene of the battle of Langside, the last contested by the unfortunate queen Mary, to regain her authority. The place where the action was fought is an eminence rising rapidly on the north and west sides, and descending very gradually on the south and west sides. On the summit is an elliptical intrenchment, commonly called queen Mary's camp; but which is undoubtedly of much higher antiquity, and probably of Roman origin. On an hill, opposite to Langside, is the old castle of Cathcart, near which queen Mary stood during the battle, and witnessed the discomfiture of her friends, and the annihilation of her hopes. On the other side of this range of hills is another ancient castle, now in ruins, which belonged to the ancestors of the great reformer Knox; and at a short distance from it, on an elevated rock, may be seen one of those green artificial hills, usually called moats. It is of a square form, the sides facing the four cardinal points; the westward rests on the precipitous edge of the steep rock; and the remaining sides are defended by a deep trench, cut out of the solid stone. Each side of this mount measures sixty feet in length at the base, and nineteen at the summit; and is twenty-one feet high. The top appears to have been a hollow square, surrounded by a parapet, with an entrance on the eastern side. No fewer than five other artificial mounts can be seen from the one described; also a Roman encampment near Paisley, distant about five miles. On the top of Barhill are the remains of a rude encampment, which occupies the summit of a precipice, formed of a perpendicular rock of a basaltic appearance, which defends it on the north; and on the south it has a parapet of loose stones. The tradition in the neighbourhood is, that it was an encampment of the celebrated sir William Wallace. The pinnacle of rock is shewn where they say Wallace sat while he enticed the English forces into a bog at the bottom of the rock, where they were all destroyed; but no historian confirms this statement. In an island of Castle-Semple loch is still to be seen the Pail or Peel, an old castle, to which the lairds of Semple were accustomed to retreat in times of unusual danger. In the lake, canoes hollowed out of single trees, like those of the Indians, have been occasionally discovered. Lower down the country the ruins of the castle of Newark chiefly claim attention. It stands on the eastern point of the bay, on which the town and harbour of Port-Glasgow is situated.

situated. When entire it consisted of a square court, with a tower at one angle, which is by far more ancient than any other portion of the building. When, or by whom it was erected, is unknown: this castle was long the property of the Dennistouns of that ilk, and afterwards came into the possession of the family of Maxwell. In this county is a variety of objects bearing the name of the renowned and patriotic Wallace, who was a native of the village of Elderslie, in the neighbourhood of the town of Paisley. See WALLACE.

The only other objects of antiquarian interest we shall mention, are four communion cups, still preserved in Kilmalcolm parish, and which were used by John Knox in administering the sacrament of our Lord's supper. They appear to have been originally candlesticks; and it was perhaps only from the necessity of the times that they were converted to this pious purpose. They are of the purest silver; and, whether from the association of ideas, or their actual fashion, have a very antique and venerable appearance. Beauties of Scotland, vol. iii. 8vo. 1806.

RENGAH, a town of Sweden, in West Bothnia; 30 miles N.N.W. of Umea.

RENGO, a town of Sweden, in the province of Tavastland; 8 miles S.S.W. of Tavasthus.

RENI, GUIDO, in *Biography*, the principal painter of the Caracci school, was born at Bologna in 1574. At an early age he became the disciple of Denis Calvart, a Fleming of great reputation, but afterwards studied under the Caracci, preferring the style of Ludovico to that of Annibal, because there appeared more of grandeur and of grace in his compositions than in those of the others.

When he left the Caracci, he went to Rome; and with a mind intent upon forming a style of art for himself, studied the works of Raphael, with which he seemed enraptured; but the vigour and force with which the recent works of Caravaggio were conducted attracted him, and for a while he attempted to follow it. Happily he was diverted from it by an observation of Annibal Caracci; viz. that the best mode of rivalling the renown of Caravaggio might perhaps arise from a different mode of art, by contrasting his confined and lamp-like effects with a broader and more ample light; and for his vulgar forms, and obscure outline, substituting clearness in the parts and forms, built upon the pure models of antiquity. This remark, made in spleen by Caracci, operated powerfully on the mind of his skillful pupil, and induced him to try its truth. He immediately devoted himself to the study of what was graceful and agreeable in form, colour, and effect; and his success is testified by numberless beautiful productions, of which we possess many in England; and France is still more rich in them.

His composition is not, however, so free from affectation as the nature of the subjects he chose demanded; the very attempt to make them graceful, too frequently militated against its object, and he substituted the grace of the theatre for that of nature. In his female heads and proportions, his model was the antique: and the character and features of the daughter of Niobe is discernible in most of them. He dressed them with becoming elegance, and executed the different parts with great freedom and truth of pencil; not unfrequently, however, in a tone of colour too light, or too leaden for flesh; with a greenish hue, which rather characterises the hand of death, or the coldness of marble, than the glowing warmth of life, and the flexible softness of nature.

His disposition of draperies was elegant; judiciously applied to the filling up of voids in the grouping of limbs,

or figures, and was wrought with the greatest freedom; yet finished with almost minute attention to the foldings. These he arranged in a grand style, but they not unfrequently exhibit the study which he bestowed upon them; and appear to arise rather from the necessities of art, than the actions of the figures. The execution of his pictures is of the most free and agreeable kind; manifesting a perfect understanding of nature; the touch being light, full, and delicate; and though they are finished very highly, yet there remains no appearance of labour. In expression, he sometimes attained the greatest perfection; as in the head of our Saviour in the Louvre, and of which the president West has a very fine duplicate: but, in general, it was rather the grace and artifice of the theatre which guided him; and his figures appear to act more than to feel. Such was the respect paid to his abilities, that he was crowned with honour and riches; but it is lamentable to add, that one vice, in which he indulged after he had passed the meridian of life, viz. gaming, robbed him of both, and reduced him to poverty and disgrace; from which he was not able to free himself during the remainder of his life, which continued till he had attained the age of 67.

In the gallery of the Louvre there are between 30 and 40 of the works of Guido, large and small, and in his various manners; and as he there comes in immediate competition with his masters, connoisseurs have an excellent opportunity of judging of his comparative merit. We have also a great many of his easel pictures in England, but they are scattered about in various collections.

RENI, in *Geography*, a town of European Turkey, in Bessarabia, on the Danube; 40 miles W. of Ismail. N. lat. 45° 23'. E. long. 28° 44'.

RENIFORME FOLIUM, in *Botany*, a kidney-shaped leaf. See LEAF.

RENITENCY, RENITENTIA, or *Renifus*, among *Philosophers*, that force in solid bodies, by which they resist the impulse of other bodies; or re-act as much as they are acted on.

RENKY, in *Rural Economy*, a term provincially signifying tall or high, when applied to animals, &c.

RENNEBAUK, in *Geography*, a river of America, in the province of Maine, which runs into the Atlantic, N. lat. 43° 20'. W. long. 70° 27'.

RENNEBO, a town of Norway, in the province of Drontheim; 36 miles S. of Drontheim.

RENNEL'S SOUND, a bay of the North Pacific ocean, on the W. coast of Queen Charlotte's island. N. lat. 53° 28'. W. long. 133°.

RENNERSDORF, a town of Silesia, in the principality of Neisse; 8 miles E. of Neisse.

RENNES, a city of France, and chief city of the department of the Ille and Vilaine; and, before the revolution, the see of a bishop, and capital of Bretagne; situated on the Vilaine, by which it is divided into two parts. It is large and populous, containing eight parish churches, besides the cathedral and several convents. The four parts which it comprehends are denominated the north-east, south-east, south-west, and north-west. The first contains 5950 inhabitants, and its canton 13,147, on a territory of 142½ kilometres, in 7 communes; the second contains 5253 inhabitants, and its canton 12,064, on a territory of 97½ kilometres, in 4 communes; the third contains 3081 inhabitants, and its canton 12,254, on a territory of 142½ kilometres, in 9 communes; and the fourth part contains 11,620 inhabitants, and its canton 14,332, on a territory of 37½ kilometres, in 3 communes. N. lat. 48° 7'. W. long. 1° 36'.

RENNET, in *Rural Economy*, a term applied to the coagulum for making cheese. It is prepared from the maw, or stomach, of the young calf, by a sort of salt pickle. It is of vast advantage in the art of cheese-making to have good sweet rennet, the particular mode of managing which may be seen under the heads **CHEESE**, **DAIRY**, and **DAIRYING**.

The preparation is formed in different modes, in different cheese districts, in the different parts of the kingdom; but mostly either in the manner of a solution, or that of a dry skin. As there is, however, much variation in the quality or strength of the different skins, it is probably the best method to reduce them into the state of a solution; as, by that means, the necessary quantity, in every case, may be the best ascertained.

In some places, it is found the most certain practice to prepare the whole of the dried maw skins, which are required for a season, at one time, by pickling and steeping them in different separate quantities of pure spring water and salt, in an open vessel, or vessels, mixing the different infusions together, and then passing them through a fine linen sieve, afterwards adding rather more salt to the whole than can be retained in the state of solution, as shewn by the appearance of some at the bottom of the vessel. The extraneous scummy matter, that comes to the surface, is continually to be removed as it rises, and fresh portions of salt occasionally supplied, as they may be wanted. In this state it is ready for use, about four ounces being sufficient for a large cheese.

In other parts, the maw skins are simply well salted, and steeped in salt pickle for some length of time; then well dried, by being spread out by means of small pieces of sticks; in which state they are made use of, by cutting pieces from the top and bottom parts of them, about the size of a half-crown for a middling-sized cheese, as those parts are in general the strongest.

And the following method of preparing rennet is practised in the northern parts of the island, and described as the most approved method in the Report on Agriculture for Argyleshire. Take the maw skin of a calf, which has fed entirely upon milk: after it is cold, wash it gently in water, fill it nearly with salt, and place it on a layer of salt in the bottom of an earthen mug. One or two more, with salt between, and a good deal above them, may be put in the same mug, and kept in a cool place, with a slate on the top, for six or eight months, or till cheese-making time next year. The skins are then taken out, and the brine allowed to drain from them; after which they are distended on small hoops or splinters put cross-wise within them, till they dry. Put the skins then in an open vessel, with three pints of pure spring water for each skin. Let them stand twenty-four hours; after which take them out, and infuse them other twenty-four hours in other water, but not more than a third of the former quantity. Mix these two infusions together, pass them through a fine linen sieve, and give them salt till the water is more than saturated, and some remain undissolved at the bottom. Rather less than a gill will serve for thirty-eight pounds of cheese. It is remarked, that, instead of two infusions, some use only one, giving four English pints to the skin, and direct the water to be first boiled, and mixed with salt into brine that will swim an egg, and then to let the heat go off till it is lukewarm, before the skin is put in twenty-four hours to steep.

It was formerly the practice to mix different kinds of aromatic herbs with the rennet; but the custom is much laid aside at present. The manner of doing it is this:

when the maw skin is well prepared, two quarts of soft pure water should be mixed with salt, in which should be put sweet briar, rose-leaves, and flowers, cinnamon, mace, cloves, and, in short, almost every sort of spice and aromatic that can be procured. Boil them gently till the liquor is reduced to three pints, taking care it be not smoked. Strain it clear from the skins, and, when milk-warm, pour it into the maw; a lemon may then be sliced into it, and remain a day or two, after which it should be strained, and put in a bottle well corked, and it will keep good for a year or more. A small quantity will turn the milk, and give the cheese a pleasing flavour.

RENNO, in *Geography*, a town of the island of Corsica; 3 miles N.E. of Vico.

RENO, a river of Italy, which rises a little to the N. of Pistoia, and runs into the Po, 4 miles above Ferrara.

RENO, a department of Italy, so named from the above-mentioned river. It consists of part of the Bolognese, and contains 199,300 inhabitants, who elect 15 deputies. The capital is Bologna.

RENOGRUND, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 59'. E. long. 23° 3'.

RENOVATOR, in *Horology*, is a watch that has the property of *renewing* the power of its main-spring, or of winding itself up, by periodic jerks that it receives from the human body in motion. Recordon of Charing-Cross, London, took out a patent for this contrivance some years ago, which is more ingenious than useful: for, while it professes to keep the watch going, without the usual winding up, so long as the watch is worn in the pocket, it foregoes the more useful property of the fusee, and renders the maintaining power very unequal at different times of the day. And should the watch remain suspended, or laid down in a state of rest, for more than 24 hours, it will cease to perform; so that instead of being a watch that will go without winding, it requires to be wound many hundred times in the day, by small successive quantities, before it will continue to perform throughout the night. We have been favoured by the inventor with a copy of so much of the specification as will suffice to give our readers an idea of the mechanism, and of its mode of action; both which we have examined, and found corresponding with the specification. Others have varied the construction; but the original, we conceive, will be deemed sufficient for us to particularize, which we will do by a reference to *figs. 1, 2, and 3, in Plate XLIII. of Horology*, which are copied from the inventor's drawing.

Exact Copy of the Specification, N° 1.—"Letter H represents a weight of silver, or other metal, which is in equilibrium in the position it is viewed, being sustained by a spiral spring fixed to its arbor, as described by *fig. 3*. In wearing the watch, or by any external motion that lifts the watch up, it loses its state of rest; and by its vis-inertiæ (matter) overcoming the strength of the spring, it yields to the laws of gravity, and falls upon the lower spring, marked *ee*. When the watch, by the motion of the body, descends, the spring *ee*, and the aforesaid spiral spring, are left at liberty to exert themselves, and return the weight upwards, till it touches the other spring *ee*; and thus, by the motion of the body, is this weight alternately thrown up and down, which turning the ratchet-wheel, marked C in *fig. 2*, which is fixed on the arbor of the weight just below the spiral spring, gathers a few teeth every motion in the wheel P, and being prevented from returning by the click M, carries forward the wheel with a pinion of 10, marked E, which turns the wheel B; which having a pinion of 12 at G, takes into and turns a wheel under the barrel A, which is fixed on the barrel arbor, and by that means is the spring wound up.

The upper part of the barrel arbor, marked *b*, has a tooth, which gains a tooth in the wheel, *a*, every revolution; and that brings the pin *c* nearer to the centre, which, when it arrives in a certain position, raises the piece *K* (*fig. 1.*), of which the centre, *B*, (not seen in the figure) is conical, in order that when the said pin *c* comes near it, it raises it with ease, and forces it into the holes, marked *N, N, N*, in the weight marked *H* (*fig. 1.*), which effectually stops its motion, and prevents the ill consequence of over-winding.

L is a cock that carries the pivot of the barrel's axis.

I is a cock that carries the pivot of the wheel *H*.

A is the barrel which carries a wheel, that catches the pinion *D*, which carries the minute-hand."

The patent was obtained in July 1780; and part 2d of the specification contains drawings, and a plan for applying the same principle to the fusee; but we do not understand that it has yet been made to answer.

REN RITH, in *Geography*, a town of Germany, in the county of Henneberg; 3 miles S. of Schleusingen.

RENS, RENSE, or *Rees*, a town of France, in the department of the Rhine and Moselle; near which, in the Rhine, is a remarkable monument of antiquity, called the "Königstuhl," or "Thronus regalis," consisting of a round vault, built of free-stone, and resting upon nine stone pillars, one of which stands in the middle. This vault is 80 feet in circumference, furnished above with seven seats, agreeable to the number of electors at that town. The ascent to it is by stairs of stone, consisting of 28 steps, and it has two strong doors. On this regal chair the electors formerly held previous consultations for some time, concerning the election of a king and emperor; and when that election could not be performed at Francfort, it was done at this place; and here were also transacted the notification and elevation of the elected personage, and also the consultations of the electors concerning the weighty matters of the empire, as well as a solemn confirmation of their privileges on the part of the emperors. Here also was established, in the year 1338, the electoral league. Maximilian I. is thought to be the last emperor who was brought hither; 5 miles S. of Coblenz. N. lat. 50° 18'. E. long. 7° 37'.

RENSEN, a lake of Prussia, in the palatinate of Culm; 10 miles N.N.E. of Culm.

RENSELAER, a county of New York, bounded N. by Washington county, S. by Columbia, E. by part of the states of Massachusetts and Vermont, and W. by Hudson river. It contains eight townships, *viz.* Troy, Greenbush, Schodack, Stephentown, Petersburg, Hofick, Pittstown, and Schaetekoke. It contains 36,309 inhabitants.

RENSELAERVILLE, or RENSELAERWICK, a township of Albany county, New York, bounded S. by Columbia county, and W. by Hudson river. In this township, opposite to the city of Albany, is a medicinal spring, combining most of the valuable properties of the celebrated waters of Saratoga.

RENT, REDITUS, in *Law*, a profit, such as a sum of money, or other consideration, issuing yearly out of lands or tenements, alienated on that condition.

The word rent, or render, *reditus*, signifies a compensation, or return; it being in the nature of an acknowledgment given for the possession of some corporeal inheritance. Co. Litt. 144.

It is thus called from the corrupt Latin, *rendita*, for *reddita*, of *redditus*; because, as Fleta tells us, *retrofit, et quotannis redit*.

The original of rents is to be sought for in the constitution of the ancient feuds, which were of a military nature,

and in the hands of military persons: however, the feudatories, being under frequent incapacities of cultivating and manuring their own lands, soon found it necessary to commit part of them to inferior tenants, obliging them to such returns in service, corn, cattle, or money, as might enable the chief feudatories to attend their military duties without distraction; which returns, or *reditus*, were the original of rents.

Under the pure feudal system, this *reditus*, return, or rent, consisted, in chivalry, principally of military services; in villenage, of the most slavish offices; and in socage, it usually consists of money, though it may still consist of services, or of any other certain profit.

Rent is regularly due and payable upon the land from whence it issues, if no particular place is mentioned in the reservation (Co. Litt. 201.); but, in case of the king, the payment must be either to his officers at the exchequer, or to his receiver in the country. (4 Rep. 73.) And strictly the rent is demandable, and payable before the time of sunset of the day in which it is reserved; though some have thought it not absolutely due till midnight. 1 Saund. 287. Prec. Chanc. 555. Salk. 578.

The usual remedy for non-payment of rent is distress; however, by the common law, distresses were incident to every *rent-service*, and by particular reservation to *rent-charges* also, but not to *rent-sec*, till the statute 4 Geo. II. c. 28. extended the same remedy to all rents alike. Moreover, by this statute it is enacted, that every landlord, who hath, by his lease, a right of re-entry in case of non-payment of rent, when half a year's rent is due, and no sufficient distress is to be had, may serve a declaration in ejectment on his tenant, or fix the same upon some notorious part of the premises, which shall be valid, without any formal re-entry or previous demand of rent. And a recovery in such ejectment shall be final and conclusive, both in law and equity, unless the rent, and all costs, be paid or tendered within six calendar months afterwards. Other remedies are action of debt, an assize of mort d'ancestor or novel disseisin, the writ de consuetudinibus et servitiis, which compels a specific payment of the rent, the writ of cessavit, and the writ of right sur disclaimer.

For an account of the rental of England and Wales, see *POLITICAL Economy*.

The lawyers ordinarily reckon three sorts of rents, *viz.* *rent-service*, *rent-charge*, and *rent-sec*.

RENT-Service, is where a man holds lands of his lord by fealty, and certain rent; or by fealty-service, and certain rent; or that which a man, making a lease of lands to another for term of years, reserveth to be yearly paid for them.

Rent-service is so called, because it hath some corporal service incident to it, as at the least fealty, or the feudal oath of fidelity. (Co. Litt. 142.) For, if a tenant holds his land by fealty, and 10s. rent; or by the service of ploughing the lord's land, and 5s. rent: these pecuniary rents, being connected with personal service, are therefore called *rent-service*. And for these, in case they be behind, or in arrear, at the day appointed, the lord may distrein of common right, without reserving any special power of distress; provided he hath in himself the reversion, or future estate of the lands and tenements, after the lease or particular estate of the lessee or grantor is expired. Litt. § 215.

RENT-Charge, is where a man makes over his estate to another by deed indented, either in fee, or fee-tail, or for term of life; yet reserves to himself, by the same indenture, a sum of money yearly to be paid to him, with a clause of distress

distress for non-payment: so called, because, in this manner, the land is charged with distress for the payment of it. Co. Litt. 143.

RENT-SEC, or *Dry-Rent*, or *Barren-Rent*, is that which a man, making over his estate by a deed indented, reserveth yearly to be paid to him, without any clause of distress mentioned in the indenture. There are also other species of rents, which are reducible to these three.

RENTS of Assize, are the certain established rents of the freeholders, and ancient copyholders of a manor; thus called, because assized and certain, in opposition to *reditus mobiles*.

Those of the freeholders are often called *chief rents*, *reditus capitales*, and both sorts are indifferently denominated *quit rents*, because by them the tenant goes quit and free of all other services. When these payments were reserved in silver or white money, they were anciently called *white rents*, or *blanch-farms*, *reditus albi*; in contradistinction to rents, reserved in work, grain, or bafer money, which were called *reditus nigra*, or *black-mail*. 2 Inst. 19.

RENT, Fee-farm, is a rent-charge issuing out of an estate in fee; of at least one-fourth of the value of the lands at the time of its reservation. (Co. Litt. 143.) *Rack-rent* is only a rent of the full value of the tenement, or near it. For a grant of lands, reserving so considerable a rent, is indeed only letting lands to farm in fee-simple, instead of the usual method for life, or years.

These are the general divisions of rent; but the difference between them (in respect to the remedy for recovering them) is now totally abolished; and all persons may have the like remedy by distress for rents-sec, rents of assize, and chief-rents, as in case of rents reserved upon lease. Stat. 4 Geo. II. c. 28.

RENTS Resolute, are reckoned among the fee-farm rents to be sold by the stat. 22 Car. II., being such rents or tenths as were anciently payable to the crown from the lands of abbeys and other religious houses; which lands, upon the dissolution of abbeys, being demised to others, the said rents were still reserved, and made payable to the crown.

RENTS, assart, chauntry, chief, gold, paschal, rack, quit, and white. See the several adjectives.

RENT, in *Agriculture*, the price paid for lands as farms by the tenants of the proprietors. The rents of lands are so extremely various, according to the nature of the soil, situation, markets, the state of the fences, buildings, and other conveniences, the ease of obtaining manures, and many other circumstances, as to be almost incapable of having any general specific prices affixed to them. They were formerly, especially in the northern parts of the island, paid in produce and personal services; but at present, according to Mr. Donaldson, over the greatest part of the island, they are paid in money, and at two periods or terms in the year. In England, Michaelmas and Lady-day are the customary terms of payment; the first payment commences six months after entry to the possession of the farm. But that in Scotland, the ordinary terms are Martinmas and Whitfuntide, or Whitfuntide and Martinmas, the tenant being allowed twelve months' credit of the first half of the rent in the one case, and in the other eighteen. And he observes, that this difference in the terms of the payment of rents is material in the purchase of landed property, being in general nearly one year's purchase in favour of England. And it is farther stated, that it was the custom of former times, in various parts of Great Britain, for the tenants to pay what was called *fore-hand* rents, that is, paying the half, and in some cases, the whole year's rent immediately

on entering to the farm, and before any benefit was derived from the possession of it. This practice is, however, now generally disused, although still kept up in some parts of Staffordshire and Perthshire, in some degree. And we believe that it still prevails in some places in Ireland. It is likewise added, that letting lands for a term of years at the former rent, but making the farmer pay a considerable sum in ready money by way of fine, was also a very common custom; but is now chiefly confined to the crown and church lands in England. This mode was evidently attended with bad consequences. By draining the tenant of all, or greatest part of his ready money, he was prevented from improving his farm. Leases of lands are considered in law as heritable property; therefore, in the event of the demise of the tenant, soon after having completed a transaction of this nature, his eldest son succeeded to the lease, and the widow and other children were of course, in many instances, reduced to poverty; all that was left to them being their proportion of the stock on this farm, and often thereby the heir was rendered incapable of keeping possession of the farm. In a word, in nine cases out of ten, it was robbing the tenant of the well-earned reward of his industry, during the existence of the former lease, and depriving him of the means of turning his new acquisition to the best account; without giving any solid advantage in return for it.

It is remarked also, that along the greatest part of the east coast of Scotland, which is the principal corn country in the kingdom, a considerable proportion of the rent of almost every farm is paid in grain and oatmeal. These articles being less fluctuating in their value than money, this appears the most equitable mode in which the rents of corn farms can be paid. It may indeed affect the farmer's interest when any sudden and unexpected rise takes place in the price of grain; but if a judgment can be given from experience, it will be found this very seldom happens. On the contrary, for these last twenty years, with only two exceptions, 1783 and 1795, the price of grain, owing to the operation of the corn laws, has been extremely moderate, while every other production of a farm has been doubled in value, and in many cases tripled. Since these periods, the price of this article has, however, risen, and continued high. The public are often essentially benefited by so great a proportion of the rents being paid in this way. Many of the proprietors have granaries erected on their estates, where, in times of plenty, they store the grain and meal which they receive from their tenants. And every person, who is in any degree acquainted with the agricultural exports and imports which take place between some districts in Scotland and others, must, he thinks, know that the supplies afforded on many occasions from these store-houses have been the means of preventing scarcity, and an unreasonable advance in the price of these articles in the large manufacturing towns and other populous places. In East Lothian, according to the agricultural report of that district, it has been suggested by some proprietors, that one half of the rent should only be paid in money, the other in kind; and assigned as a reason, that the profit or loss arising from any material, as the rise or fall in the price of grain, would, in that way, be equally divided between the landlord and tenant. This is a mode probably founded on equity and justice. And it is further stated, by the first writer, that in the most northern parts of Scotland, the rents are, to a certain extent, paid in personal services. The tenants are bound to plough and harrow a certain portion of the landlord's farm, to reap, carry home, thresh, dress, and mill a certain quantity of the crop. They are also bound to pay poultry, eggs, butter, cheese, sheep, swine, linen

linen yarn, fish, &c. ; in a word, they are more the slaves of the landlord than their own masters.

These are shameful feudal practices, which the proprietors of such lands should remove as soon as possible, as without it their interests must suffer greatly from the lands remaining without improvement. Besides, it is a species of bondage highly disgraceful to civilized society. The able author of the Agricultural Report of the county of Argyle in Scotland, thinks that all services, whether paid to the master or to any under him, should be entirely abolished; and all rents formed into one sum of money, including public burdens, such as ministers' stipends, schoolmasters' salary, road money, &c. Thus, says he, the tenant would have always a clear view of the amount of his rent, and save time and trouble, and perhaps expence, by having to settle with one only instead of many. His time is precious, and should never be thrown away without necessity.

In regard to the parliamentary and parochial taxes, they may be said to be paid, the first writer says, by the tenants over the greatest part of both kingdoms; and many leases contain a clause, he observes, binding the tenants to pay, not only all the taxes that are imposed, but also all that may be imposed. But, he thinks, that it appears absurd that the proprietors, whose interest it is to attend to the increase or decrease of all such taxes as more immediately concern their property, should devolve the payment of those taxes on their tenants. They must know, that whoever pays them in the first instance, to them the lands are of less value, in consequence of such taxes having been imposed. They ought also, he thinks, to consider that their influence might be the means of keeping the most extravagant of them, such as the tithes and poors' rates, within more reasonable bounds, than it is to be expected the utmost exertions of the tenants can be able to effect. And that, further, proprietors could ascertain the value of their property with more minute exactness, were they, on the one hand, to receive from their tenants the full rents which their lands are worth, and, on the other, pay all taxes to which they are subjected. The interest of agriculture, and the ease and comfort of the farmers, would at the same time, he thinks, be essentially promoted, were they relieved from these teasing exactions and compositions with which they are so frequently molested, particularly in this part of the kingdom.

And he suggests, in respect to the general price of renting lands, that when it is considered how many circumstances operate in determining the rent of land, and how much these frequently vary in the same parish or lordship, it will be found impossible to form any correct idea in regard to the rents payable by the acre for the various kinds of soil over the whole island. Any conjecture that may be formed (for the subject admits, he says, no more) must be vague and incorrect. It is supposed, that the remarkable change that has taken place in the situation of the kingdom and the manners of the people, by the abolition of the feudal system, the increase of commerce, manufactures, and agricultural improvements, with the immense additional quantity of paper-money introduced within these few years into circulation, have had the effect of enlancing both the value and rent of lands. While these flourish, and paper-money supports its nominal value, lands in property or lease must necessarily, he thinks, continue to advance. But that, should any cross accident interrupt the former, or depress the value affixed to the latter, the recent great advance in the rent of lands, in various parts of the island, would render such calamities more universal in their effects, and of course of more serious consequence to the country.

The rent of land is kept up by a great variety of local

causes, as the particular nature of the farms, their extents, the goodness of the roads and markets, the convenience of canals and other sorts of water carriage, and many other circumstances of a similar nature. In dairy and grass districts, as well as some others, rents are kept up by the particular modes of occupation, in many instances. Many little advantages are connected with the former; while the latter has not any heavy expences to contend with. Small farms are constantly higher rented than those of the larger kind. Convenient carriage and large markets are always favourable to rents. Local convenience has invariably great influence in raising the rent of land. In short, it has been suggested by an able writer, that every sort of improvement in agriculture, as well as manufactures, has a tendency to advance the rent of land; and that, if, to the practical excellence of the former, improvements in the latter should be added, with a more extended commerce, rents may be raised to an extraordinary degree. While the contrary of these matters is calculated to reduce the quantity of wealth, and, of course, to lower the rent of land; consequently rent rises and falls with the prosperity or declining state of the agriculture, the manufactures, and the commerce of the country, the former of which is only to be preserved by peace.

But though the rents of land have been greatly increased within these few late years, it is probable that they must feel the effects of the vast load of taxation and other charges which bear so hard upon agriculture at present.

But the ascertaining of the rents of lands in the different districts of the kingdom is a point of considerable importance both in a political and agricultural view, as by such means the produce of them may be better and more certainly calculated.

Mr. Smith, in his valuable Agricultural Survey of Argyleshire, states, that the quality of the soil is there extremely different; so that such valuations as have been lately made, differ, sometimes on the same farm, from 2s. to 15s. the acre of arable ground. The pasture, too, being partly green hill, but mostly heath, differs no less in its quality than the arable land. Some of it is valued below 4d. and some above 4s. the acre. In the neighbourhood of Campbellton, a few spots of arable land let from 2l. to 3l. the acre. But this price may be said to be put, not altogether upon the land, but partly upon the accommodation. But what proportion the rent of a farm should bear to its produce, depends so much on soil, climate, situation, and other circumstances, that no general rule can, he thinks, be laid down on the subject. In regard to arable lands more particularly, it is a common, though perhaps not a just remark, that one-third of the produce should go for rent, one-third for expence and management, and one-third for the farmer's profit, interest, &c.

But Mr. Middleton remarks, that the method practised by some gentlemen, of estimating the produce of land by trebling the rent, is very fallacious: three times the rent is not by any means equal to the value of the produce of the land under the best system of husbandry now in use; though under the old exploded course of fallow, wheat, oats, in the scanty produce of common fields, and when taxes and the expences of living were at one-half of the present amount, it was not very distant from the truth. But under the more improved courses of husbandry on land, at and under twenty shillings an acre, the produce is now, he thinks, more generally worth from five to seven times the rent.

In the North Riding of Yorkshire, as stated in the report of that district, the average rent of farms of pretty good soil is from 15s. to 21s. per acre, in which there may be land rated

RENT.

at from 5*s.* to 35*s.* per acre, so that the average value of a farm will vary according to its proportion of good and bad land. Some farms of the latter kind may be let as low as 5*s.* per acre, and some let cheaper at 30*s.*; so great is the inequality of the soil, that nothing accurate on this head can be stated. Near large towns, land for convenience in small parcels, and in the aggregate to no great amount, is let at 3*l.* or 4*l.* per acre.

But in the western district of that county, as about Skipton and Settle, the lands were found to let as high as 40*s.* and 50*s.* the acre; while from the best information in the corn part of the county at the same time, 20*s.* and 30*s.* were considered as a high rent, and in many places it was still much lower.

In Shropshire, the rents of lands, where the roads are bad, and the grounds little improved, are from 8*s.* to 12*s.* the statute acre, and in more favourable districts and situations, from 15*s.* to 20*s.* the farm together. But near towns, the price is much higher, as from 2*l.* to 6*l.* the acre.

And in Norfolk, according to Mr. Young, in the light sand district, as marked in the Survey, the average price of letting is 6*s.* the acre; the various loams at 16*s.*; the better sands at 12*s.*; the rich loams 26*s.* and the marsh land clays 28*s.* In Suffolk the several soils are stated to be rented as below, the whole county included, sheep-walk, waste commons, &c. which are very large deductions from the rate of the cultivated lands:

	<i>s.</i>	<i>d.</i>
Strong, wet loam, per acre - - -	13	0
Rich loam - - - - -	14	0
Sea district of sand - - - - -	10	0
Western district of ditto - - - -	5	0
Fens - - - - -	2	6

But in all the districts, with the exception of the fen, there are tracts that are let at 20*s.* to 25*s.* and even higher, especially meadows.

In the county of Essex, the average rent of good landed farms may be stated at about 20*s.* or 25*s.* the acre. They have lately increased very much in some places.

In Suffex, good land is rented at from 20*s.* to 30*s.* the acre, but there is a great deal let at much lower rents.

Land has risen much of late years in many parts of the country.

In the county of Oxford, the rent of land is very various. The red land lets on the average at 30*s.*, the miscellaneous loams at 25*s.*; the stone-brash at 20*s.*; and the Chiltern at 16*s.* the acre. There are, however, large portions of land let at still lower rents in different parts.

In Cheshire, the land averages full 30*s.* the acre in rent as farms; and in Lancashire, the rent of land is equally as high, if not higher.

In the very south-western district of Cornwall, the rents of land fluctuate very greatly, as from 5*s.* to 50*s.* the acre in farms properly so named. The circumstances affecting rents here, besides the quality of the soil, and the aspect or situation, are the vicinity to sea sand, and to market towns. There are instances of land letting very high in particular situations, as at 13*l.* the acre about Penzance. And in the same parishes the rents of land sometimes vary from 8*l.* to 5*s.*; nay, even on the same farm, not exceeding 150 acres, some parts are worth 50*s.*, and others not 5*s.* the acre.

The neighbourhood of towns and large markets, as well as of extensive manufactories, has, in all cases, a tendency to raise the rent of land, whether as farms or otherwise, in every part of the kingdom.

In all parts of Scotland, even in the Highlands, the rise of rents has been gradual and progressive for many years, and in some places they have been more than doubled within these last twenty-five or thirty years.

It has been stated by Mr. Collingsworth, of Daventry, in the fourth volume of Communications to the Board of Agriculture, that in respect to the principle of increasing rents, where liberty is given to break up old grass or pasture lands that are under lease, that he has known, within this five years past, a double rent given for leave to plough up an old pasture for cropping for three years; and that consequently it appears to him that a statement of the expences and profits upon arable and pasture lands should be severally made out, to ascertain by how much the balance of profit of the one exceeds that of the other. He therefore states them, upon a probable calculation, in the following manner:

TABLE of Expences.

	1.		2.		3.		4.		5.		6.		7.

Tillage produce	54	0	0
Ditto expences	35	0	6

6)18 19 6(= 3l. 3s. 3d. profit per acre for the farmer.

Grazing Expences.

	<u>£</u>	<u>s.</u>	<u>d.</u>
Rent and taxes per acre	1	15	0
Labour ditto	0	10	0
	<u>2</u>	<u>5</u>	<u>0</u>

Grazing Profit.

	<u>£</u>	<u>s.</u>	<u>d.</u>
A bullock and a half to three acres, at 5l. per head	7	10	0
Three sheep upon ditto, at 25s. per head	3	15	0
	<u>11</u>	<u>5</u>	<u>0</u>

Grazing produce of three acres	11	5	0
Ditto expences of ditto	6	15	0

3)4 10 0(= 1l. 10s. 0d. profit per acre to the grazier.

	<u>£</u>	<u>s.</u>	<u>d.</u>
Then say, grazing profit per acre.	1	10	0
To which add for grafs seeds	1	0	0
The additional rent to make up the sum as per contra, will be	0	13	3
	<u>3</u>	<u>3</u>	<u>3</u>

By this means the rent that can be afforded to be given may be ascertained with tolerable correctness in many instances of farming. See *GRASS Land*.

The author of the Argyleshire Agricultural Survey, after remarking that there is very little arable land in that county but which is capable of higher cultivation, besides the great quantity of waste ground that may be improved in almost every farm, says, that the land is therefore capable of being made to yield a much higher rent when better cultivated; though not a great deal of it, as is generally thought, can bear much more, in the present stage of improvement, than what is laid on already, unless it be under a different management, which in sheep lands might be by the introduction of better woolled breeds, and in arable lands by adopting a better system of husbandry.

It is conceived, that the idea of high rents being a spur to improvement and exertion, is a common, and, to a certain extent, a just maxim. No doubt there may be some who, if they had the land for nothing, would be ruined by their indolence. But the more common case is, that when a tenant sees that all his exertions will not do, he becomes dispirited and desperate, and allows himself to be carried along by the stream which he cannot stem. The land

suffers, the tenant fails, the farm gets a bad name, and the rent must be lowered. Thus the landlord, as well as the tenant, suffers, by raising the rent higher or faster than the improvement of the land will bear. But he adds, that a substantial tenant is generally cautious of engaging to pay a rent that is exorbitant. He sees the success of those who invest their money in other branches of business; and he follows their example, if he has not the prospect of a farm's yielding him full interest for his money, and an adequate return for his diligence and labour. Whereas he who has least to lose, is often the most forward to offer, and the landlord is often tempted to accept the offer, without considering that a capital is necessary for paying the rent, and improving the land. Instances of ruin to the tenant, and loss to the landlord, from too high rents, are not unfrequent, especially on some of the smaller estates. Most of the farmers toil hard, live poorly; and for one who has a trifle for his pains, perhaps two give their pains for nothing. Many who have old leases obtained before the late rise in land, and in its produce, took place, are very well, as are also many of those who have sheep stocks; as their possessions are managed with less expence, and the value of some of them was not well known till they were tried under the sheep system. But even bad

bargains are become good by the late rise on every article of produce; and most of these who have leases are at present at their ease.

It is concluded that the occupiers of land, whether in pasturage or tillage, ought certainly to be able, like labourers or tradesmen, to live by their occupation, and to support their families by their daily care and labour. The interest of money invested in their stock, with the proper allowance for tear, wear, and risk, they should be able to save as a provision for their families, and for old age; as the money so invested would give this return, if laid out on interest, without any trouble whatever. It cannot be considered as any part of the produce of the ground; and therefore no part of it ought, in equity, to enter into the payment of the rent; and yet not one in ten, perhaps, is able to save it; nor do they commonly advert that so much ought to be saved in justice. They are generally satisfied if they can keep their stock undiminished; so that the business, in general, returns much less to those engaged in it than almost any other. A happy predilection in favour of the occupation in which they were brought up, is, he thinks, what induces so many to follow it. Perhaps it may be also said, that there is implanted in the human mind, for wise purposes, a certain innate disposition, or instinct, which leads it to delight in rural occupations.

These remarks should be well attended to by the proprietors of farms, as their advantages, as well as that of their tenants, may be greatly promoted by such means.

In regard to the receiving of rents where they are of different kinds, as for cottages, tithes, in the form of compositions, chief rents, quit rents, and some other sorts, besides those of the farm kind, they require some attention and method, such as the fixing of distinct times in the same, or different days, for the reception of each, when on a large scale, so that the exact times of attendance for each may be known to those who have any thing to settle. So far as farm rents are concerned, the fixing of proper periods for receiving them is of great importance, though the matter has hitherto been little attended to, there being often no fixed time known to the holders, until signified by the precept of the receiver. And that is, in many cases, liable to alteration. This is very inconvenient to the farmers in many instances, as they must either sell their corn and live-stock to great disadvantage, many times, before it was necessary, and have large sums of money lying uselessly by them, or meet the receiver, perhaps, with only part of the rent. The propriety and necessity of having certain exact times for receiving rents are therefore evident, and, of course, the most suitable times for these are to be ascertained, as whatever enables the holders of land to turn their produce to the most advantage, increases the prosperity of the farms, and ultimately benefits the proprietor.

In this country it is said, by the author of the work on Landed Property, farm rents mostly become due at Lady-day and Michaelmas. But the proper times of paying them depend on the marketable produce of the land, and the season of the year at which it goes, and can be best sold in the markets. The holders of farms should never be forced to improper regulations in these respects, or be suffered to withhold the payment of their rents when they have obtained the money for their produce.

Upon corn farms, which are numerous in most parts of this country, Michaelmas is the most improper time in the whole year to call upon tenants for their rents. It is at the close or height of harvest, as the situation may be, when their pockets are drained by extra expensive labour, and when the grain cannot be threshed out to replenish them; also when

much of the off-going live-stock is not ready for the market.

In the county of Norfolk the above writer paid great attention to this matter, and found that there, the latter end of February, or beginning of the succeeding month, was the most proper season for Michaelmas farm rents to be paid; and the month of June for those of Lady-day. And, by correct examinations, those most proper in other places may be found, keeping the above principles constantly in view. Farmers should never be obliged to do any thing improper in the disposal of their articles at unsuitable seasons or markets, or to raise money in any improper ways; nor be led into speculations with money while it lies idly by them.

The best seasons having been ascertained, the exact periods are to be fixed on, from the particular nature of the farms, the customs of the districts in respect to fairs and the dealers in different sorts of produce, which may generally be readily managed without much difficulty.

RENT Accounts, such as are kept on estates, whether of farms, cottages, chief rents, or any other sorts of annual payments, by the managers. They should be clear and comprehensive, containing every thing of importance about them, as their different circumstances may direct.

The management of the farms, in rent accounts, whether yearly or half yearly, must be the same as in the receiving rentals, as they appear on the general map; and as they naturally lie on the face of the estate, according to the ideas of the writer of the work on Landed Property. See *MAP of Estates*.

The parishes, or manors, lying wholly or partially within the estate, are to be first geographically arranged, and then the farms on the same principle as they lie within the respective parishes. In this way it is constantly the same, and has the advantage of not being liable to be disturbed by changes of any sort, which affords much facility and convenience in all such accounts on many occasions.

RENT Charges, the fixed payments to which an estate or farm is subject to, such as chief rents, quit rents, annuities, endowments, schoolmasters' salaries, charitable donations, &c.

RENT Days, the particular days or times when the rents of estates or farms become due. They should, in all cases, be exactly and properly fixed as to season and other circumstances. See *RENT*.

RENT-Roll, a general statement of the gross annual income of an estate, or receivership, whether it arises from farms, woods, lands, quarries, cottages, or any other similar things; or from tithes, quit rents, or any other sort of rents, &c.

In forming rent-rolls, this sort of general view of income is best arranged, according to the writer of the work on Landed Property, in columns, as being the most plain and perspicuous; and for a schedule of farms, the following heads are proper. First, the numerals identifying the several farms in the general map. Secondly, the names of the farms. Thirdly, the contents or admeasurement of each. Fourthly, the names of the present holders. Fifthly, the amount of the existing rents. Sixthly, the amount of the outgoing, if any payable by the proprietor. And, seventhly, the expirations of the terms, if any. The farms should be arranged according to their situations.

In the receiving of rentals, they are the particulars. These are few where the rents are regularly paid, the farms under proper management, and the holders pay the taxes and repairs. But it may be necessary to see in the receiver, at one view, the name of the farm, and the name of the holder, as well as the amount of his half year's rent.

And where arrears are suffered, and, of course, accounts created, more particulars are necessary, such as the name of the farm and the tenant, his arrear at the last payment, his half year's rent, and any other charge that may be against him, as well as any allowance which is to be made to him, and the neat sum that is receivable—a blank being left for the sum received, and another for the arrear left. These things should be done in the manner of the best accountants, the arrangements being made in the same way as the rent-roll with an alphabetical index.

RENTA, in *Geography*, a lake of Albania, near Scutari.

RENTAL, a roll in which the rents of a manor are written and set down, and by which the lord's bailiff collects the same; it distinguishes the lands and tenements, and the names of the tenants, the several rents arising, and for what time, usually a year. See *RENT-Roll*.

RENTER WARDEN, an officer in most of the companies of London, whose business is to receive the rents or profits belonging to the company.

RENTERBACH, in *Geography*, a river of Saxony, which runs into the Elbe near Wittenberg.

RENTERIA, a town of Spain, in Guipuscoa; three miles S.E. of St. Sebastian.

RENTERING, FINE-DRAWING, in the *Manufactories*, the sewing of two pieces of cloth, edge to edge, without doubling them; so as that the seam scarcely appears at all: hence it is called *fine-drawing*.

The word is formed from the French, *rentraire*, which signifies the same thing; and which Menage, after Salmasius, derives from the Latin, *retrahere*, of *re*, *in*, and *trahere*, by reason the seam is drawn out of sight, and covered.

Serges, &c. are to be sewed: cloths fine-drawn. The author of one of the *Let. Edif. et Cur.*, speaking of the great dexterity of the fine-drawers in the East Indies, assures us, that if you tear a piece of fine muslin, and give it one of them to mend, it shall be impossible for you to discover the place where it is rejoined, even though you had made a mark to know it by.

The dexterity of our own fine-drawers, though inferior to that above-mentioned, is nevertheless such, as puts them in a condition to defraud the king, by sewing a head or slip of English cloth on a piece of Dutch, Spanish, or other foreign cloth; or a slip of foreign cloth on a piece of English, so as to pass the whole, as of a piece; and by that means avoid the duties, penalties, &c. The trick was first discovered in France by M. Savary, author of the *Diction. de Commerce*.

To *renter*, in *Tapestry*, is to work new warp into a piece of tapestry damaged, eaten by the rats, &c. and on this warp to restore the ancient pattern, or design. The warp is to be of woollen, not linen. Among the titles of the French tapestry-makers, is included that of renterers.

Fine-drawing is particularly used for a rent, or hole, happening in the dressing or preparing of a piece of cloth, artfully sewed up or mended with silk.

All fine-drawings are reputed defects or blemishes; and ought to be allowed for in the price of the piece. Hence, M. Savary establishes it as a rule, which is certainly founded on natural equity, that every manufacturer mark the fine-drawings of his cloth with a piece of packthread tied to the list; to direct the draper to the spot: and that the draper appraise the taylor, or other person to whom he sells it, of the same, that he may not come to damage in the cutting; there being instances of drapers condemned to take back their cloth, when cut to pieces, for omitting to mention the fine-drawings, and other flaws.

On this occasion, M. Savary extols the procedure of an

English merchant, who, sending a piece of cloth damaged in one spot, to his correspondent at Paris, put a piece of gold in the damaged place, to make up the damage. But as this example is perhaps the only one of its kind, that author recommends it to the merchant, or draper, to unfold all the pieces entirely, as they come to him; to discover the fine-drawings, and other flaws, in order to make the clothier accountable for them.

RENTERSHAUSEN, in *Geography*, a town of the duchy of Wurzburg; 7 miles E. of Lauringen.

RENTOWN, a town of Scotland, in Dumbarntonshire, considerable for its manufactures; 5 miles W. of Dumbarnton.

RENTRE'E, Fr. in *Music*, a return to the subject of a musical composition, after a pause, or some excursion or deviation from the theme; or in a fugue, an imitation of some particular passage or design.

RENTY, in *Geography*, a town of France, in the department of the straits of Calais, on the Aa; 9 miles S.S.W. of St. Omer.

RENTZ, a town of the island of Rugen; 11 miles S.S.W. of Bergen.

RENUENTES, in *Anatomy*, a pair of muscles of the head, thus called as being antagonists to the annuantes; and serving to throw the head backward, with an air of refusal.

From their situation they are also called *rectus capitis*, major et minor.

RENVERSE', Fr. in *Music*. With respect to intervals inverted, this term is opposed to direct. (See *DIRECT*.) With respect to chords, it is opposed to *fundamental*; which see.

RENVERSE', *inverted*, in *Heraldry*, is when any thing is set with the head downward, or contrary to its natural way of standing: thus, a chevron renversé is a chevron with the point downwards.

The same term they also use when a beast is laid on its back.

RENVERSED VOLTE. See *VOLTE*.

RENVERSEMENT, Fr. in *Music*, an inversion in the order of sounds which compose the chords, and in the parts which constitute the harmony: which is done by substituting, by octaves, treble notes for the base, and base notes for the treble. It is certain that every common chord has a fundamental and natural order pointed out by the harmonics of a single string, a great bell, or organ pipe. (See *HARMONICS*, and *RESONANCE*.) But the circumstances of the succession, taste, expression, selection of notes for melody, variety, approximation of the harmony, frequently oblige a composer to change this order, by inverting the chords, and consequently the disposition of the parts. As any three things may be arranged in six different ways, and four things in twenty-four ways, it seems at first as if a common chord was susceptible of six changes, and an accompanied discord of twenty-four; as the one is composed of three sounds, and the other of four; and that the inversion only consists in the transposition of octaves. But it must be remembered, that in harmony a change in the upper parts is not regarded as an inversion, provided the base or fundamental sound remains the lowest. Thus, these two orders of sounds, *Ceg*, or *Cge*, are not regarded as inversions of the harmony. And in the chord of the 7th no change in the upper parts constitutes an inversion.

As long as the fundamental sound is the lowest part, the order is direct. But when this order is changed, or the fundamental sound is given by transposition to one of the upper parts, the harmony is inverted. In whatever part a discord is prepared, it must be resolved by the same part;
a sharp

a sharp 7th must ascend, a flat 7th must descend; false relations must be avoided. This is the key to the chief mysteries of composition. Binding notes in syncopation in the treble and base must be differently treated: in the 9th the chord is direct; in the 2d it is inverted, the discord being in the base.

Upon the organ, and other keyed-instruments, inversions are necessarily made for the convenience of the hand, in giving different faces to the same chord. See FACE.

RENVERSING. See REVERSING.

RENUKA, or RENUCL, in *Mythology*. See RUNEKA.

RENUNCIATION, RENUNCIATIO, the act of renouncing, abdicating, or relinquishing any right, real or pretended.

Renunciations are sometimes *express*, as by contracts, &c.; sometimes *tacit*, as by contrary acts.

To renounce an inheritance, a community, &c. is to pass a solemn act before a notary, or public officer, by which a person declares he will not intermeddle in an inheritance, or profit in a company; but surrenders his part, and quits all pretensions.

RENVOI, Fr. in *Music*, a reference to a strain, or part of a strain that is to be repeated; either implied by dots in the spaces of the staff, or by an $\$$ dotted, which is the initial of *segno*, Ital. a sign. See REPEAT.

RENWEZ, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Mézières; 7 miles N.W. of Mézières. The place contains 1202, and the canton 6061 inhabitants, on a territory of 140 kilometres, in 16 communes.

REOLLE, LA, a town of France, and principal place of a district, in the department of the Gironde. N. lat. $44^{\circ} 35'$. E. long. $0^{\circ} 2'$.

REORDINATION, REORDINATIO, the act of conferring orders on one already ordained.

The ceremony of ordination impresses what the divines call an indelible character; and cannot, therefore, be repeated: yet is reordination practised in England, with regard to the dissenting ministers, who conform to the church; the bishops pretending that they alone have a right to confer holy orders, and that every priest or minister, who does not receive them at their hands, has no lawful or regular vocation.

This has formerly proved a great obstacle to the re-union of those ministers to the church of England; many of whom, otherwise disposed to conform, have scrupled to be re-ordained; inasmuch as re-ordination implies their former vocation to be null; that they had administered the sacraments without any right thereto; and that all their ministerial acts were invalid.

In the 11th century, the crime of simony having been very flagrant, many people fell into the error to believe, that the simoniacal bishops could not ordain validly, and those who had received orders at their hands should be re-ordained. The people of this opinion made a party of themselves, and were distinguished by the title of "Reordinantes."

REORTHE, LA, in *Geography*, a town of France, in the department of the Vendée; 13 miles W. of Châtaigneraie.

REPAIR a Statue, To, or other piece of sculpture, is to touch up a statue, &c. (cast in a mould) with a chisel, graver, or other instrument, to finish the places which have not come well off.

To REPAIR a Cast, figure, or the like, they clear off the barb, and what is redundant in the joints and projections. See STATUE.

To REPAIR a Medal, is to retouch it; so as, from rusty and defaced as it was, to render it clean, neat, and perfect. In order to this, they take off the rust with a graver, touch up the letters, polish the ground, and raise and restore the figures which before were sometimes scarcely seen. When the figures are eroded or broken, they fit a piece of cement on the spot; and on this cut with a graver so dexterously, that the figures appear entire, and well kept; yet nothing spoils medals so much as repairing them. See MEDAL.

To REPAIR a Ship, is to amend any injuries, or supply any deficiencies, which a ship may have received by age, battle, tempestuous weather, &c. The repair is necessarily greater or smaller in proportion to the loss or damage the vessel has sustained. Accordingly a suitable number of the timbers, beams, or planks, or a sufficient part of either are removed, and new pieces fixed in their places. The whole is completed by *breaming*, *calking*, and *paying* the body with a new composition of itself.

REPAIRERS, artificers who chase figures and beautify sword-hilts, &c.

REPAIRING, in *Building*, &c. See REPARATION, and RESTAURATION.

The repairing of large walls, doors, ceilings, coverings, &c. belongs to the proprietor or landlord: the tenant is only charged with small repairs, as glazing windows, locks, &c. by the French called *locative* repairs.

REPAIRS, in *Hunting*, are the haunts and places which the hare runs to.

REPAIRS of Farm Buildings, in *Rural Economy*, the necessary means of putting and keeping them in proper order. This properly belongs to different sorts of workmen, as masons, carpenters, &c. It is a bad practice to let buildings of this nature fall much into decay, as by such neglect a great deal of expence is frequently incurred that might otherwise have been avoided. See FARM-BUILDINGS.

REPANDUM FOLIUM, in *Botany*, a leaf whose outline is undulating, without the surface, or substance, being otherwise than even. See LEAF, where, for *nyphaoides*, read *nympheoides*.

REPARANDIS PONTIBUS. See PONTIBUS.

REPARATION, REPARATIO, the act of repairing, re-establishing, retrieving, or mending a building, or other work, damaged, or gone to decay.

The enemy repaired the breach as soon as it was made. The establishment of turnpikes is for repairing of the roads. An ecclesiastical patron is by ancient custom obliged to repair the choir or chancel of a church, and the parishioners the nave.

REPARATIONE FACIENDA, in *Law*, is a writ which lies in divers cases, *e. gr.* where there are tenants in common, or joint tenants of a house, &c. which is fallen to decay, and the one being willing to repair it, the other two will not; in this case, the party willing shall have this writ against the other two.

REPARO, in *Geography*, a small island near the coast of Brasil. S. lat. $29^{\circ} 23'$.

REPART, in the *Manege*, is to put a horse on, or make him part a second time.

REPARTEE. See REPARTY.

REPARTITION, REPARTITIO, a dividing or sharing a thing a second time.

REPARTY, or REPARTEE, a ready, smart reply: especially in matters of wit, humour, or raillery.

The word in the original French, *repartie*, has the same signification.

Wicquefort observes, that there is a great difference between

between a free, sprightly reparty, and an offensive *sarcafism*; which see.

REPAST, REPASTUM, a meal or refection, taken at a stated hour.

In old law-books repast is particularly used for a meal's meat given to servile tenants, while at work for their lord.

The French call their meal *repast*; the Latins, *pastus*; the Italians and Spaniards, *pasto*.

In antiquity the repasts were frequently sacrifices; for which reason we find them often prepared by kings themselves.

REPEALING, in *Law*, the revoking or annulling of a statute, deed, or the like. See ABROGATION, REVOCATION, &c.

No act of parliament shall be repealed in the same session it was made in. A deed or will may be repealed for a part, and stand good for the rest.

Brook uses the word *repellance* in the same sense.

REPEAT, in *Music*, a character shewing that what was last played or sung must be repeated, or gone over again.

The repeat serves instead of writing the same thing twice over. There are two kinds of repeats; the *great* and the *small*.

The *great* repeat is only a double bar, dotted on each side; or two parallel lines drawn perpendicular across the staff; with dots on either hand. See its form under CHARACTERS of *Music*.

This mark shews, that the preceding strain is to be repeated; that is, if it be near the beginning of the piece, all hitherto sung or played is to be repeated; or, if towards the end of a piece, all from such another mark.

In gavots, we usually find the repeat at about the third part of a piece; in minuets, borees, courants, &c. towards the end.

Some make this a rule, that if there be dots on each side the bar, they direct to a repetition both of the preceding and the following strain; if there be only dots on the side, then only the strain on that side is to be repeated.

The *small* repeat, is where only some of the last measures of a strain are to be repeated: this is denoted by a character set over the place where the repetition begins (see CHARACTERS, in *Music*), and continues to the end of the strain.

When the song ends with a repetition of the first strain, or part of it, instead of a repeat, they use the word *da capo*, *i. e.* from the beginning.

REPEATING CIRCLE, an instrument used in *Naviga-tion*, *Astronomy*, and *Surveying*. This instrument derives its name from the property it has of giving the average of several repeated measures of an angle, made round the whole circle, so as to diminish the errors of division and of eccentricity; which is a very useful property, where the art of dividing is not brought to that perfection which it is in England. When the lunar method of determining the longitude, by the help of improved tables of the moon's motion, was proposed to be put in practice, Mayer offered a construction of the circle, which, by repeating the measure of a lunar distance, promised to increase the accuracy with which such distance could be measured; and after him, Borda went a step farther towards the attainment of the desired object, both whose contrivances we have described under our article CIRCLE. These instruments, like Hadley's octants, measured the angles by reflection, and were consequently used at sea; but the principle of repetition is not confined to reflecting instruments; and Borda constructed, or contrived the construction of, a repeating circle, which will measure either vertical or horizontal angles without reflection, with a degree of accuracy that has placed it high

in the estimation of the French, among whom accurate dividing is yet a desideratum. This instrument we have also described, and likewise Troughton's improvement on it, in the article already referred to.

But the repeating principle was extended by Joseph de Mendoza Rios in the reflecting circle, so as to measure both backwards and forwards, and to give *double* results by means of a moveable or *flying* circle, which we have likewise described under the article CIRCLE, together with our observations on the peculiarities of its construction. It remains, therefore, that we now describe a recent construction of a reflecting and repeating circle, contrived by professor Hafsler of Philadelphia, who is a native of Switzerland, and who has resided several months in London, for the purpose of collecting superior astronomical and surveying instruments, at the expence of the American government. The object of this ingenious foreigner was to unite the repeating principle of Borda, with the firm construction of Troughton's reflecting circle, so that his new instrument might be free from the objections of the repeating circles that preceded it, arising from shallow centre-work, and clamping after the contacts were made in an observation; and in the construction he has adopted, by the aid of Troughton, he has rendered his instrument free from these objections, and given it every advantage which its original contriver contemplated: we cannot, however, admit, that in practice it is superior in accuracy, and certainly not in simplicity, to Troughton's *reflecting circle*, which we have before described, as giving the average of six readings at two operations, in inverted positions, at the different sides of zero on the fixed circle. The union of Borda's and Troughton's constructions is thus effected by Hafsler; the circular border of Troughton's instrument is made moveable round the centre, like his three armed verniers, and is graduated like his, while a pair of opposite verniers move round the same centre, above the plane of the moveable or flying circle, having a clamping apparatus for slow motion at one of the two opposite verniers, so that the pair of verniers may be made to revolve with or without the graduated flying circle; another pair of verniers, similar to the former, and having also a clamping apparatus for slow motion, are made fast to the frame, and have the extreme ends of their connecting diametrical bar united by a graduated semicircle, that lies under the flying circle, and is hid thereby when the graduated face of the circle is uppermost; the use of this semicircle is, to receive a pair of sliding pieces of brass that act as stops to the indices, when they are properly placed at the rough angle, to the right and left of zero on the flying circle, by a previous operation; so that, when the bar of the verniers comes in contact with either of these stops, it is known, even in the dark, that the place where a contact is to be made is nearly ascertained, and the vernier-bar may be made fast, for the screw of slow motion to be brought into action to complete the contact. The principle on which the measurement is effected is this; the revolving verniers move forward from zero of the graduated circle, when the stops are previously set to the rough angle, till the index or vernier-bar touches the stop to the left, when the graduated face is uppermost, and is clamped to the fixed verniers; the clamping apparatus then fixes the verniers, and the tangent-screw completes the contact; the two revolving verniers might now give the angle, by two readings, but the repeating principle has not yet been introduced, and consequently no advantage is yet derived from this first observation, over a common circle with a double vernier; the fixed verniers are in the next place unclamped, but as they have no motion, the flying circle and revolving verniers are brought back to the right together, across the point zero, till

REPEATING CIRCLE.

till the vernier-bar touches the second stop, and during this motion, the revolving verniers have moved backwards just *double* the rough distance with the attached circle, that they did forwards before without it; consequently the fixed verniers will now read the same angle at the right of zero, that the revolving verniers did on the left, when the clamping is again made and the contact completed; but still this is only a second mode of reading a single measure of the angle, and nearly all that is yet gained in accuracy, is the extermination of the index error, and that of the dark glass, if used; these errors having been alternately positive and negative, if any existed. These two measures, separately read, are equivalent to Borda's *crossed* observation, as he calls it, because the motion of the vernier-bar *crosses* the point zero in his fixed circle: here it is presumed that the two objects, that include the angle, are equally luminous; but if not, it will be necessary to invert the face of the instrument before each second, fourth, sixth, &c. contact, and then the motions will all be forward, or from right to left, which otherwise would be alternate: the second reading, however, may be omitted; the revolving verniers, being unclamped, must be moved again to the first stop in the original position, where, the contact being complete, they will give a *double* measure if examined; but the readings are yet omitted: the fixed verniers are now unclamped, the instrument again inverted, and the contact completed, when these verniers, if examined, will also give double measures; and thus treble and quadruple measures must be had successively at both the revolving and fixed verniers, or even more, if the circle has not been passed over by each pair of verniers, before the readings are required to be examined, and then the average of all the measures by the fixed verniers, added to an average of all the measures by the revolving verniers, will afford the means of getting an average of the whole number of measures.

From this description of Hafsler's mode of applying the repeating principle, it will be obvious to the reader, that the diametrical bars of the two pair of verniers must not be contiguous to each other, when the glasses called the horizon-glass and index-glass are parallel; and accordingly we find, on examining an instrument of this construction, that these bars cross one another at right angles before the operations begin; but as there is but one zero in the circle, one pair of the verniers must necessarily begin at 90° , when the other pair begins at 0 ; consequently ninety degrees must be deducted from the sum of the measures of this pair before their average is taken: otherwise, if neither pair of the verniers begin at zero, the two numbers from which they respectively commence must both be deducted before the averages are taken, in which case it will be of no importance at what part of the flying circle the operations begin. Should the reader find any difficulty in comprehending this description of Hafsler's repeating circle, without a reference to a drawing, we recommend that he refer to our account of reflecting circles, described under the article CIRCLE, where he will find the account of the two separate instruments of which this forms an union; and at the same time will see how it differs from Mendoza's, which gives *double* results.

By way of illustrating the use of Hafsler's repeating circle, we will suppose that some known star is to the east or west of the moon, and that the longitude of the place of observation is required from an actual measurement of the distance of the said star from the moon's limb, when compared with its computed distance as given for a certain hour on the same evening at Greenwich, in the Nautical Almanac: we will suppose the glasses of the circle adjusted, and the small telescope screwed into its socket, and so adjusted both

for distinct vision, and comparative brightness of both objects, that the star can be brought to touch the moon's limb, and have a sensible contact; in the first place, hold the plane of the circle in such an inclined position that it may pass through both objects, and get the star into the field of view, while the revolving verniers are at zero, and the fixed ones clamped at 90° ; in the next place, move the revolving verniers with an equable motion, and let the eye follow the star, or rather the image of it, till it comes to the edge of the moon, which it may be made to approach by a proper motion of the body; then clamp the index there till the stop is put on the semicircle very nearly to touch the edge of the index, where it must remain; the second stop must also be put to the same division on the semicircle at the other side of its zero, provided this zero be co-incident with the zero of the circle; or, which is the same thing, the distance between the stops must be somewhat more than double the angle to be measured; the contact may now be completed by the tangent-screw; let the fixed verniers be unclamped, and the released circle and revolving verniers be made to recede together till the second stop gives them a check, there they must be clamped and the circle inverted, when the star will again be seen nearly in contact, which must now be made entirely so by the screw of slow motion; in the next place the moveable verniers, being first unclamped, must be carried again to the first stop and clamped, to make the contact as before, after the inversion of the circle has again taken place; and in this manner the revolving verniers must be moved to the first stop, and the verniers and circle together to the second stop, before each inversion and contact, till five, six, seven, or more alternate operations have been gone through, and the whole circle has been travelled over, which may always be known from the position of the stops. The exact times must be noted at the beginning and end of these operations, which by an expert observer will be gone through in a few minutes, and the mean time will be had of the moment corresponding to the mean of the repeated observations: at these times the assistants must also take each their two altitudes. Say now that the stops were required to be nearly at 40° at each side of zero of the semicircle, or that the distance between them was 80° , within a few minutes over, and that there were nine observations thus made with the revolving verniers, and eight with the fixed ones, which numbers suppose the first and last measures to be taken with the same pair of verniers, or with the same face of the circle uppermost; say also, that the final readings by this pair of verniers were respectively $1^\circ 10' 20''$, and $181^\circ 10' 0''$, or rather $361^\circ 10' 20''$, and $541^\circ 10' 0''$, because these verniers completed the entire circle; then if we diminish the latter reading by 180° , its distance before the other, we shall have $361^\circ 10' 0''$, and the average of the pair of opposite verniers will be $361^\circ 10' 10''$, which quantity divided by 9, the number of measures taken by them, will give a quotient of $40^\circ 7' 8''.9$ for the first average of the distance, resulting from the operation of the revolving verniers alone; again, let the final readings of the fixed verniers be respectively $50^\circ 57' 20''$ and $230^\circ 57' 30''$; but if we increase the first reading by 360° , we shall have $410^\circ 57' 20''$, which must be diminished by 90° , because it started from this number, and the remainder will be the correct reading, namely $320^\circ 57' 20''$; also $230^\circ 57' 30''$ increased by 360° is $590^\circ 57' 30''$, and this number diminished first by 90° , as before, and then by 180° , the distance by which it precedes its fellow-vernier, will be $320^\circ 57' 30''$, and consequently the average of the two final readings of the fixed verniers will be $320^\circ 57' 25''$, which sum divided by 8, the number of repeated

peated measures in the inverted position, will give a quotient of $40^{\circ} 7' 10''.6$ for the distance averaged by the fixed verniers; and lastly $\frac{40^{\circ} 7' 8''.9 + 40^{\circ} 7' 10''.6}{2} = 40^{\circ} 7'$

$9''.75$, the exact apparent distance, which may be converted into the true distance by any of the methods used for clearing it of the joint effect of *parallax* and *refraction*. See *LONGITUDE*, and *LUNAR Observations*.

REPEATING Mechanism, in *Horology*, is a mechanical contrivance that, when acted on by a pull or push, will make the striking part of a clock or watch repeat the hours and quarters of existing time, so that a person in the dark, or even in bed, may know within a quarter of an hour what it is o'clock, as well by night as by day. The first contriver of the repeating mechanism of a clock was Barlow, a London clock-maker, who in the year 1676 produced to the world his specimen of ingenuity, which astonished all the admirers of the mechanical arts, and excited in others a desire to vary the construction, with a view to the improvement of the original contrivance; and the consequence has been, that Quare, Tompion, and others in London, as well as after them Julien le Roy, Thiont, Collier, Larcay, Berthoud, &c. on the continent, have given so many different kinds of repetition, for both clocks and watches, that a particular description of each construction would require several plates, and a whole volume to give the details. Under our article *CLOCK* we have already explained at considerable length the particulars of the repeating mechanism of two several clocks, as it is constructed at this time, from which the reader will see how the acting parts may be varied in many ways to answer the same purpose; but in most of the modern contrivances the *rack* and the *snail* constitute the basis of the plan, and regulate the action of all the metallic parts employed. For the repeating mechanism of a watch, see our article *WATCH*.

REPELLENT MEDICINES, are those which prevent such an afflux of fluids to any part as would excite tumour or inflammation, or which tend to diminish such an afflux, when it is already produced. Medicines of this quality are principally refrigerants and astringents, especially the former. The most effectual repellent is cold; and those applications, therefore, which most effectually obstruct the heat, are the most efficacious repellents; and many of the drugs, which are applied in combination with cold liquids, are of little value; the cold menstruum, that is the water, being the principal agent in the curative process.

REPELLING POWER, *vis repellens*, in *Physics*, is a certain power or faculty residing in or exerted by the minute particles of natural bodies, by which, under certain circumstances, they mutually fly from each other.

This power is the reverse of the attractive power.

Sir Isaac Newton having established the attractive power of matter from observation and experiment, argues, that, as in algebra, where positive quantities cease, there negative ones commence; so in physics, where the attractive force ceases, there a repelling force must begin; and adds, that there is such a force, does likewise appear from observation.

As the repelling power seems to arise from the same principle as the attractive, only exercised under different circumstances, it is governed by the same laws: now the attractive, we find, is stronger in small bodies than in great ones, in proportion to the masses; therefore the repelling is so too. But the rays of light are of all others the most minute bodies we know of; therefore, of all others, their repelling force must be the greatest.

Sir Isaac Newton computes, that the attractive force of the rays of light is above 100000000000000 times as strong as the force of gravity on the surface of the earth: hence arises that inconceivable velocity with which light (if it consist of real particles) must move, to reach from the sun to our earth in seven minutes. For the rays emitted from the body of the sun by the vibrating motion of its parts are no sooner got without the sphere of attraction of the sun than they come within the action of the repelling power.

The elasticity or springiness of bodies, or that property by which, after having their figure altered by an external force, they return to their former figure, follows from the repelling power. See *REPULSION*.

REPENTANCE, in *Theology*, is a change of sentiments followed by a change of conduct: or repentance denotes such a conviction of the evil and danger of a sinful course, as is sufficient to produce shame and sorrow in the review of it, and effectual resolutions of amendment. This definition expresses the sense of the two words *μεταμελεια* and *μετάνοια*, which are commonly used by the evangelical writers to signify repentance.

REPENTIGNY, in *Geography*, a town of Canada, on the river St. Laurence. N. lat. $45^{\circ} 48'$. W. long. $73^{\circ} 15'$.

REPERCUSSION, in *Mechanics*. See *REFLECTION*.

REPERCUSSION, in *Music*, iteration, a repetition of the same note or sound.

This often happens in the modulation, where the essential chords of each mode, or of the harmonical triad, are to be struck oftener than the rest; and of these three chords, the two extremes, *i.e.* the final and the predominant one, (which are properly the repercuSSIONS of each mode) oftener than the middle one.

REPERNDORF, in *Geography*, a town of the duchy of Wurzburg; 7 miles S.E. of Wurzburg.

REPERTORY, *REPITORIUM*, a place in which things are orderly disposed, so as to be easily found when wanted.

The indices of books are repertories, shewing where the matters sought for are treated of. Common-places are a kind of repertories, very useful to the learned.

REPITORIUM Anatomicum, denotes a large hall near an amphitheatre of dissections, where skeletons, both human and brutal, are orderly preserved. Such is the repertory in the French king's garden at Paris.

REPETEND, in *Arithmetic*, is used for that part of an indeterminate or infinite decimal fraction, which is continually repeated ad infinitum.

Thus, in the indeterminate decimal fraction 317.45 316 316,316, &c. the figures 316 are called the repetend.

These repetends often arise in the reduction of vulgar fractions to decimals, thus $\frac{1}{3} = 0.3333$, &c. $\frac{1}{7} = 0.142857$, 142857, &c. $\frac{1}{11} = 0.0909$, 09, &c.

Decimals of this kind are called repeating or circulating decimals, (which see,) on account of this continual repetition or circulation of the same figures. Infinite decimals are of two kinds, which may be distinguished by the general denominations of certain and uncertain. A general infinite decimal is such whose numerator runs into infinity by a continual repetition of one or more figures, as 44, &c. 033, &c. Uncertain decimals are such, whose numerator goes on for ever without a constant circulation of figures. The essential difference between these two kinds is this; that the certain infinite decimals have a determinate, finite, and certain value, in that there is a certain determinate vulgar fraction, which expresses the true and complete value of that infinite decimal, whereas the uncertain have no such finite and assignable value: and hence the reason of the names.

REPETEND, *Single*, is that where only one figure is repeated, as in 0. 3 3 3, &c.

REPETEND, *Compound*, is that where two or more figures are repeated, as in 0. 09 09, &c. or in 0. 142857 142857, &c.

Decimals with repetends may always be reduced to vulgar fractions; for either the repetend begins with the decimal, or not.

If the repetend begins with the first place of decimals, or if the decimal is a pure circulate, make it the numerator of a vulgar fraction, and make the denominator consist of as many 9's as the repetend has figures; or if there be cyphers between the point and repetend, with as many cyphers to the right hand of the denominator, then will this vulgar fraction be equal to the decimal.

Thus, if the repetend be single, as in 0. 3 3 3, the vulgar fraction equal to it will be $\frac{3}{9} = \frac{1}{3}$. So if the repetend be compound, as in 0. 09 09, &c. the equivalent vulgar fraction will be $\frac{99}{99} = \frac{1}{1}$.

And in like manner 0. 142857 142857, &c. = $\frac{142857}{999999} = \frac{1}{7}$.

The reason is obvious from this consideration, that the decimal 0. 3 3 3, &c. is $\frac{3}{10} + \frac{3}{100} + \frac{3}{1000}$, &c. the sum of which will be equal to $\frac{3}{10}$ divided by $1 - \frac{1}{10} = \frac{9}{10}$ = $\frac{1}{3}$; and so of the rest.

If the repetend does not begin with the first place of decimals, but at some place farther on towards the right, or if it be a mixed circulate, as in the decimal 0. 8 3 3 3, &c. where the repetend does not begin till the second place of decimals, observe, that 0. 8 3 3 3 + &c. = $\frac{8}{10} + \frac{3}{100} + \frac{3}{1000} + \frac{3}{10000}$ + &c. = $\frac{8}{10} + \frac{1}{10} \times \frac{3}{10} + \frac{3}{100} + \frac{3}{1000}$ + &c. = $\frac{8}{10} + \frac{3}{10}$ = $\frac{11}{10}$; and so of the rest. Therefore the proposed decimal is $\frac{11}{10} + \frac{1}{10} \times \frac{1}{10} = \frac{11}{10} + \frac{1}{100} = \frac{111}{100} = \frac{11}{10}$.

Thus also if the decimal 0. 2 27 27, &c. were proposed, we shall find it = $\frac{2}{10} + \frac{27}{100} + \frac{27}{1000} + \frac{27}{10000}$ + &c. And $\frac{27}{100} + \frac{27}{1000} + \frac{27}{10000}$ + &c. being $\frac{27}{99} = \frac{3}{11}$, the decimal will be =

$\frac{2}{10} + \frac{3}{11} \times \frac{1}{10} = \frac{2}{10} + \frac{3}{110} = \frac{22+3}{110} = \frac{25}{110}$. The reason

of which is obvious from what has been said.

It may, perhaps, be worth while to observe, that if the numerator of a vulgar fraction be unity, and the denominator any prime number, except 2 and 5, the decimal equal to the proposed fraction will always be a repetend, beginning at the first place of decimals; and this repetend must necessarily be a submultiple, or an aliquot part of a number expressed by as many nines as the repetend has figures; that is, if the repetend have six figures, it will be a submultiple of 999999; if four figures, it will be a submultiple of 9999, &c. From whence it follows, that if any prime number be called *p*, the series 9999, &c. produced as far as is necessary, will always be divisible by *p*, and the quotient will be the repetend of the decimal fraction = $\frac{1}{p}$. For the management of decimals

of this kind, see Malcolm's Arithmetic, book v. chap. 4.

REPETITION, REPETITIO, the reiterating of an action. See REITERATION.

Habits are acquired by the frequent repetition of actions.

School-philosophers call the repetition of the same numerical effect, in another place, the replication of that effect.

REPETITION. The French make use of this word for a *rehearsal*, which the Italians call a *prova*. "Rehearsals (says Rousseau) are necessary for compositions that are to be performed in public, in order to prove whether the

several parts are correctly copied, and for ascertaining the entrances and the exits of the several characters, as well as to see that they seize the spirit of their parts, and of the entire drama. Rehearsals are likewise of use even to the composer himself, to enable him to judge of effects, and to make such changes as may seem necessary."

REPETITION, in *Music*, denotes a reiteration or playing over again of a composition, whether it be a whole strain, or part of a strain, or a double strain. The repetition is denoted by a character called a *repeat*; which is varied so as to express the various circumstances of the repetition.

REPETITION, *Reply*, is also used when, after a little silence, one part repeats or runs over the same notes, the same intervals, the same motions; in a word, the same song, which a first part had already gone over during the silence of this.

REPETITION, *Reply*, is also a doubling or trebling, &c. of an interval, or reiteration of some concord or discord.

Thus, a fifteenth is a repetition of the octave, *i. e.* a double octave, or second octave.

REPETITION of *Passages*. See ROSALIA.

REPETITION, in *Rhetoric*, is a figure by which the orator rehearses the same words or phrases over again.

Of this there are two kinds. In the first, the word is repeated precisely in the same sense: as, *Oh, Jerusalem, Jerusalem, who killest the prophets, &c. My God, my God, why hast thou forsaken me?*

Such repetitions have the same effect in discourse, with second strokes of the pencil in painting; they render the colours more strong and lively.

Sometimes the orator begins again and again with the same word, of which we have an instance in the beginning of Cicero's first oration against Catiline: *Nihilne nocturnum præsidium palatii, nihil urbis vigilia, nihil timor populi, nihil consensus bonorum omnium, nihil hic munitissimus habendi senatus locus, nihil horum ora vultusque moverunt?* Where the word *nihil* is often reiterated gives an admirable force and vehemence to the discourse. Again, the same author: *Quem senatus damnarit, quem populus R. damnarit, quem omnium existimatio damnarit, eum vos sententiis vestris absolvetis?* Again, *Non feram, non patiar, non sinam.*

The second kind of repetition, called *πλοκε*, *place*, (which see,) is a repetition of the same word in the same phrase; but in such a manner, as that some new idea or character is added to the word in the second, which it had not in the first.

As, *Corydon is always Corydon: Ex illo Corydon Corydon est tempore nobis*; by which we signify, that Corydon is no ordinary person; and that nothing can distinguish him but the repetition of his own name: as if we should say, *he is Corydon, that is enough*. By the same figure our Saviour speaks, when he says: *Let your language be yea, yea; and nay, nay*. See RECAPITULATION.

REPETITUM, or *Vetium Namium*, in *Laz.* See NAMIUM.

REPHAM, or REEPHAM, in *Geography*, a market-town and parish in the hundred of Eynsford, and county of Norfolk, England, is situated at the distance of 13 miles N.W. by N. from Norwich, and 112 N.E. by N. from London. The charter for its market, which is held on Saturday weekly, was obtained by sir John de Vaux, in the fifth year of the reign of king Edward V. An annual fair, on the 29th of June, was granted at the same time. At one period this parish was remarkable for having three churches situated within one sepulchral inclosure; *viz.* Reepham, Whitwell, and Hackford; but only two of these are now standing.

The church of Reepham serves also for the village of Kerdeston, which belongs to the same lords. In this edifice was formerly a "famous image of the Virgin Mary," which, like the shrine of Diana at Ephesus, was productive of no small gains to its possessors; numerous pilgrimages having been made to it by persons of rank and affluence. Here are several monuments to the memory of different branches of the Kerdeston family. One of them, placed against the north wall of the chancel, bears the figure of a knight templar in armour, with his hands and legs crossed. It has no inscription, but is traditionally said to have been raised in honour of sir Fulk de Kerdeston, who died in 1270. Blomefield's History, &c. of Norfolk. Beauties of England and Wales, vol. xi. by John Britton, F.S.A.

REPIN, a river of Poland, which runs into the Dnieper, near Kiev.

REPITZ, or ROPITZ, a town of Saxony, in the margravate of Meissen; 2 miles N. of Torgau.

REPLANTING, in Gardening, the act of planting a second time.

The gardeners used to displant their tulips every year, and replant them. Lettuces must be displanted and replanted yearly, to make them head and knit. If strawberries, &c. be not displanted and replanted once in a few years, they degenerate.

REPLEADER, REPLACITARE, in Law, is to plead over again what was once pleaded before.

If, by the misconduct or inadvertence of the pleaders, the issue be joined on a fact totally immaterial, or insufficient to determine the right, so that the court upon the finding cannot know for whom judgment ought to be given, the court will after verdict award a replader, *quod partes replacitent*; unless it appears from the whole record that nothing material can possibly be pleaded in any shape whatsoever, and then a replader would be fruitless. (4 Bur. 301, 302.) And whenever a replader is granted, the pleadings must begin *de novo* at that stage of them, whether it be the plea, replication, or rejoinder, &c. in which there appears to have been the first defect, or deviation, from the regular course. Raym. 453. Salk. 579.

REPLEGIANDO *Homine, Writ de.* See HOMINE.

REPLEGIARE *de Averiis*, a writ brought by one whose cattle are distrained, and put in a pound, by another; upon security given the sheriff to pursue, or answer the action at law against the distrainer.

REPLETION, in the Canon Law, is where the revenue of a benefice or benefices is sufficient to fill or occupy the whole right or title of the graduate, who holds them.

When there is a repletion, the party can demand no more by virtue of his degrees. In England, where benefices are not appropriated to degrees, repletion, strictly speaking, has no place.

In France, by the old constitution, 600 livres, or 45l. sterling *per annum*, made a repletion, when the benefice was obtained otherwise than by a degree; and 30l. *per annum*, when it was obtained by virtue of a degree.

REPLETION, in Medicine, sometimes signifies the general fulness of the habit, which is called *plethora*; and sometimes the temporary overloading of the stomach with food and drink, which occasions particular attacks of disease, such as a fit of apoplexy, or of the gout, or a diarrhœa.

REPLEVIN, PLEVINA, in Law, a remedy granted on a distress; being a re-deliverance of the goods distrained to the first possessor, on security or pledges given by him to try the right with the distrainer, and answer him in the course of law.

If a person distrain another's goods or cattle for rent, or

damage feasant, &c. the owner, upon giving security to the sheriff, that he will prosecute his action against the party distraining, and return the goods or cattle again if the seizure shall be adjudged good, may have a writ of *replevin*, or *replegiari facias*. See DISTRESS and REPLEVIN, *infra*.

REPLEVISH, is to let one to mainprise upon surety. See MAINPRISE.

REPLEVIN, REPLEVIE, (from the Latin *replegiare*, to re-deliver to the owner upon pledges of surety,) is the bringing of a writ of *replevin*, or *replegiari facias*, issuing out of chancery, by him whose cattle or goods are distrained by another upon any cause; having first given security to the sheriff, that, on the delivery of the thing distrained, he will prosecute the action against the person who made the distress.

In the stat. 24 Henry VIII. we read of *canes replegiati*, or *bounds replevied*, in a case between the abbot of St. Alban's and Geoffrey Childwic.

Goods may be replevied two ways; *viz.* by writ, which is that used by the common law; and by *plaint*, which is that by statute law, for the more speedy having again the cattle and goods; and is brought in the sheriff's court.

Accordingly, the statute of Marlbridge (52 Hen. III. cap. 21.) directs, that (without suing a writ out of chancery) the sheriff, immediately upon complaint made to him, shall proceed to replevy the goods. And, for the greater ease of the parties, it is farther provided by statute 1 P. & M. cap. 12. that the sheriff shall make at least four deputies in each county, for the sole purpose of making replevins. Upon application, therefore, either to the sheriff, or one of his said deputies, security is to be given, in pursuance of the statute of Westm. 2. 13 Edw. I. cap. 2. 1. That the party replevying will pursue his action against the distrainer; for which purpose he puts in *plegios de prosequendo*, or pledges to prosecute: and, 2. That if the right be determined against him, he will return the distress again; for which purpose he is also bound to find *plegios de retorno habendo*. Besides these pledges, which are merely discretionary in the sheriff, the statute 11 Geo. II. cap. 19. requires that the officer, granting a replevin on a distress for rent, shall take a bond with two sureties, in a sum of double the value of the goods distrained; which bond shall be assigned to the avowant or person making cognizance, on request made to the sheriff; and, if forfeited, may be sued in the name of the assignee. The sheriff, on receiving such security, is immediately, by his officers, to cause the chattels taken in distress to be restored into the possession of the party distrained upon; unless the distrainer claims a property in the goods so taken. If this be the case, the party replevying must sue out a writ *de proprietate probanda*. But, if no claim of property be put in, or if (upon trial) the sheriff's inquest determines it against the distrainer, then the sheriff is to replevy the goods, if they be found within his county. When the goods are delivered back to the party replevying, he is then bound to bring the action of replevin, which may be prosecuted in the county-court; but either party may remove it to the superior courts. Blackst. Comm. book iii.

REPLICATION, REPLICATIO, in Logic, the assuming or using the same term twice in the same proposition; otherwise called *reduplication*,

Some philosophers use the phrase *replisatio mundi*, replication of the world, for its conversion, or turning round. The human soul is said to be in a place *replicatively*, *replisativè*, when conceived to be all in the whole, and all in every part of it.

REPLICATION, in Law, is an exception of the second degree,

gree, made by the plaintiff to the plea or first answer of the defendant.

The replication is particularly that which the plaintiff replies to the defendant's answer in chancery; and which is either *general* or *special*. The special is grounded upon matter arising out of the defendant's answer, &c. The general is so called from the general words used in it. See REJOINER, and CONFESS and avoid.

REPLIQUE, Fr. in *Music*. This term, which implies an octave, has been, not very happily, rendered into English by *replicate*, in the wretched translation of Rameau's treatise; but though it has been generally adopted, it has never seemed properly naturalized to our language. Sir Francis Bacon has used the word *recurrence* for the same purpose, which is much more congenial with our idiom. There is necessarily a repetition of the same found, or its octave, in every composition of four parts.

REPLLOT, in *Geography*, one of the Quarcken islands, in the gulf of Bothnia. N. lat. $63^{\circ} 15'$. E. long. $21^{\circ} 7'$.

REPOLON, in the *Manege*, is a demivolte, the croupe in, closed at five times. The Italians are extremely fond of this sort of manege. In making a demivolte, they ride their horses short, so as to embrace or take in less ground, and do not make way enough every time of the demivolte.

REPOLOVSKOI, in *Geography*, a town of Russia, in the government of Tobolsk, on the Irtysh; 171 miles N. of Tobolsk.

REPOSE, Fr. in *Music*, the answer to a subject of fugue. The answer to a fugue, and the time when it is to be introduced, are difficulties in the art of regular fugue, concerning which young contrapuntists are long doubtful. See FUGUE and COUNTER-SUBJECT.

REPORT, the relation made upon oath, by officers or persons appointed to visit, examine, state, or estimate any thing.

Damages, repairs, &c. are judged from the reports of experienced persons. Provisions for persons wounded are only granted on the reports of surgeons, &c.: in cases of rape, the report of matrons is to be had.

REPORT, in *Law*, is a public relation, or bringing to memory, which is judicially argued, debated, resolved, or adjudged, in any of the king's courts of justice, with the cause and reason of the same delivered by the judges. They are histories of the several cases, with a short summary of the proceedings, which are preserved at large in the record, the arguments on both sides, and the reasons the court gave for its judgment: taken down in short notes by persons present at the determination: these serve as indexes to, and also to explain, the records.

These reports, which in matters of consequence and nicety the judges direct to be searched, are extant in a regular series from the reign of king Edward II. inclusive; and from his time to that of Henry VIII. were taken by the prothonotaries, or chief scribes of the court, at the expense of the crown, and published annually; whence they are known under the denomination of the "Year-books." And it is much to be wished (says judge Blackstone) that this beneficial custom had, under proper regulations, been continued to this day; for though king James I., at the instance of lord Bacon, appointed two reporters, with a handsome stipend, for this purpose, yet that wise institution was soon neglected; and from the reign of Henry VIII. to the present time, this task has been executed by many private and contemporary hands; who sometimes through haste and inaccuracy, sometimes through mistake and want of skill, have published very crude and imperfect (perhaps contradictory) accounts of one and the same determination. Some of the

most valuable ancient reports are those published by lord chief justice Coke, which are so highly esteemed, that they are generally cited without the author's name; and are styled *καὶ ἐξοχῶν, the reports*. The reports of judge Croke are also cited in a particular manner, by the name of those princes in whose reigns the cases reported in his three volumes were determined, viz. queen Elizabeth, king James, and Charles I., as well as by the number of each volume. Blackst. Com. book i. &c.

When the chancery, or any other court, refers the stating of some case, or comparing an account, &c. to a master in chancery, or other referee, his certificate therein is also called a report.

REPORTS, in *Military Matters*, are daily, weekly, and monthly reports of the state of the companies or regiments, relative to their being present or absent, on duty, sick, confined, &c.

General officers report to the commander-in-chief only. The commander-in-chief's guard reports to himself by one of his aid-de-camps. Reports of cavalry are given in to the senior generals of cavalry; and reports of infantry to the senior general officers of infantry. On a march the field officer of the piquet reports to the general of the day who leads the column; and in camp to the next superior officer to himself. A provost martial gives in his return of prisoners, and reports to the general of the day.

Deputy judge advocates, acting in districts or garrisons, &c. send in the minutes of courts martial, and report to the judge advocate general, without going through any general officers. Regimental surgeons report to their commanding officers, and surgeons in districts, &c. to the medical board.

The life-guards report, through the Gold Stick, to the king direct, from whom they receive the parole.

The foot-guards report, through the field officer of the day, to the king direct.

All other troops belonging to the British service, the marines excepted, who report to the admiralty, report through their several commanding officers, &c. to the adjutant-general and secretary at war, and to the commander-in-chief.

A *special* report is said to be made when the name of an officer is transmitted by his commander to the general of a district, independent of the regular returns; and some specific instance of misconduct is laid before him. It must be generally remembered, that every officer, on his arrival from abroad with a regiment or detachment of troops, must report himself to the governor or commanding officer of the seaport at which he arrives; and every officer who takes his passage for foreign service, must do the same previous to his departure.

The senior officer in each recruiting quarter reports weekly to the field officer of the district, the number and strength of the parties therein. The field officers commanding recruiting parties in districts, report to the inspector-general, to whom all returns and reports are to be transmitted by them, and not direct from the recruiting officers.

The various subordinate reports are those of a rear-guard, of a barrack-guard, of a quarter-guard, of a main-guard and its dependencies, &c. &c.

In the column of remarks which must accompany each of these reports, it is necessary, for the person who signs, to specify all casualties and extraordinary occurrences according to the particular nature of each report. The different hours at which the grand rounds, visiting rounds, and patrols went, must likewise be put down.

REPORT, *Pinion of*. See PINION.

REPOS, Fr. in *Music*, a repose, or pause. It is the termi-

termination of a phrase or period. The repose here meant resembles a hyatus in versification; it is a cadence more or less perfect as the base falls a third, a fifth, or rises to the sixth of the key. It is a kind of resting place, determined by the sense of the passage, and by feeling. See *CADENCE* and *CADENZA*.

REPOSE, in *Poetry*, &c. See *REST*, *PAUSE*, &c.

REPOSE, in *Painting*, is applied to certain masses, or large systems of assemblages of light and shade; which, being well conducted, prevent the confusion of objects and figures; by engaging and taking up the eye so as it cannot attend to the other parts of the painting for some time; and thus leading it to consider the several groupes gradually, and, as it were, to proceed from stage to stage.

REPOSE, *In*, in *Military Language*, is a phrase that applies to troops which are allowed to be stationary for any given period, during an active campaign, either through sickness, or from some other cause.

REPOSITION of the Forest (formed from *re*, and *ponere to lay again*), an act by which certain grounds, before made purlieu, are, upon a second view, laid to the forest again.

REPOSITION, in *Surgery*, the reduction of a bone.

REPOSITORY, *REPOSITORYUM*, a store-house or place where things are laid up and kept. In which sense we say, the repository of the royal society, the royal repository at Woolwich, containing models of every sort of warlike stores, &c. See *MUSEUM*.

REPOSITORY of Farm Manure, in *Rural Economy*, the place where it is put or laid up. See *RECEPTACLE of Stall Manure*.

REPOSO, in *Geography*, a small island near the coast of Brazil; S. lat. 19° 36'.

REPPELE, a town of Hinder Pomerania; 7 miles W.S.W. of Zachau.

REPPIN, a town of Brandenburg, in the New Mark, on the Eylang; six miles S.S.W. of Drossen, N. lat. 52° 25'. E. long. 15° 2'.

REPREHENSION, in *Rhetoric*. See *PARRHESIA*.

REPRESENTATION, *REPRESENTATIO*, in the *Drama*, the exhibition of a theatrical piece; including the scenes, machines, recitation, &c.

Sir Richard Steele's principle is, that the design of a play is not to be read but represented; so that it is on the stage, not in the press, it is to be judged of; and that the pit, not the public, are the proper judges.

REPRESENTATION, in *Law*. See *DESCENT*, *Right of Crown*, *INTESTATE*, *ADMINISTRATION*, and *PARLIAMENT*.

REPRESENTATION, in *Insurance*, is understood to mean a collateral statement, either by parol or in writing, of such facts or circumstances relating to the proposed adventure, and not inserted in the policy, as are necessary for the information of the insurer, to enable him to form a just estimate of the risk. Such representations are often the principal inducement to the contract, and afford the best ground upon which the premium can be calculated. A representation may be untrue, either wilfully and fraudulently; or inadvertently and innocently.

A wilful misrepresentation, or *allegatio falsi*, in any fact or circumstance material to the risk, is a fraud that will always avoid the contract. As if an agent, knowing that a ship had sailed from Jamaica for London on the 24th of November, effect an insurance on the voyage, and tell the underwriter that the ship sailed in December: this is a fraud, and the policy is void.

And such misrepresentation so completely vitiates the policy, that the insured cannot recover upon it, even for a

loss arising from a cause unconnected with the fact or circumstance misrepresented. As if the insured represent that the ship or goods insured are neutral property, when in fact they are enemy's property; he shall not recover even for a loss occasioned by shipwreck.

So it would be if the broker or agent were to assert that a ship or goods were neutral property, without knowing whether this were true or false, and they are, in fact, enemy's property: for, though it may not, perhaps, be equally criminal *in foro conscientie* for a man to aver that to be true which he knows nothing of, as to aver that to be true which he knows to be false; still it is unquestionably a fraud, and in the case of an insurance, equally injurious to the underwriter; because he is induced by the deception, however occasioned, to compute the risk upon false principles. The same reasoning holds even in the case where the person himself making the representation believes it to be true.

But if he were only to say that he believes the ship to be neutral property, knowing nothing on the subject, and having no reason to believe the contrary; there, though the ship be not neutral, the representation will not avoid the policy; because the underwriter may inform himself of the grounds of this belief, before he enters into the contract; and if he neglect to do so, he takes upon himself the risk of its being unfounded.

For the same reason, if the word *expected* be used, this will not amount to a representation: as when a broker in getting insurances effected on several ships, belonging to the same owner, and speaking of them all, said, — 'Which vessels are expected to leave the coast of Africa in November or December,' when, in fact, they had all sailed in the May preceding: this does not amount to a representation, being only an *expectation*, the ground of which the underwriter might have enquired into.

There is a material difference between a representation and a warranty. A warranty, being a condition upon which the contract is to take effect, is always a part of the written policy, and must appear on the face of it: whereas a representation is only matter of collateral information or intelligence on the subject of the voyage insured, and makes no part of the policy. A warranty, being in nature of a condition precedent, must be *strictly and literally* complied with; but it is sufficient if a representation be true in *substance*. By a warranty, whether material to the risk or not, the insured stakes his claim of indemnity upon the precise truth of it, if it be affirmative, or upon the exact performance of it, if executory; but it is sufficient if a representation be made without fraud, and be not false in any material point; or if it be *substantially*, though not *literally*, fulfilled. A false warranty avoids the policy, as being a breach of a condition upon which the contract is to take effect, and the insurer is not liable for any loss though it do not happen in consequence of the breach of the warranty. A false representation is no breach of the contract, but if material, avoids the policy on the ground of *fraud*, or at least because the insurer has been misled by it.

It has already been shewn that a warranty must appear upon the face of the policy, and make a part of the written contract; and therefore a written paper, wrapped up in the policy, or even waded to it, is only a representation. For the same reason, the written instructions for effecting the policy, unless inserted in it, cannot be deemed a warranty, but only a representation; for the underwriter, by not insisting on having these instructions inserted in the policy, shews that he is content to take them as a representation.

REPRESENTATION.

But it behoves all agents and brokers concerned in the effecting of policies, to keep correct entries of these instructions, and indeed of all representations made to the under-writers: for the whole question between the insured and the under-writers often turns upon these instructions. Besides, they are answerable to the insured for the consequences of any representation made by them without authority, as well as for those of omitting to make such representations as they have been instructed to make.

By an extension of equitable relief in cases of fraud, it seems to be now settled that if a false representation be made to the first under-writer on the policy, in a material point, this shall be considered as a misrepresentation made to every under-writer, so as to infect the whole policy, otherwise it might be a contrivance to deceive many; for when a respectable under-writer stands first on the policy, the rest subscribe the policy without asking a question; and if the first under-writer be imposed upon, the rest are entrapped by the same fraud.

But the insurer must avail himself of this sort of objection in the first instance; for after a verdict has been obtained, the court will not set it aside upon an affidavit of the first under-writer, that a material misrepresentation had been made to him. The defendant, in such case, knows what has been represented to himself, and might have known what had been represented to the first under-writer; and he shall not lie by till after a trial, in order to make the objection, if the verdict should be against him.

If the insured state his computation as *fact*, instead of the information on which he founds his computation, and it prove untrue, it is a misrepresentation; and if material, it will avoid the policy.

A misrepresentation in a material point equally vitiates the contract, whether it be the misrepresentation of the insured himself or of his agent, and whether it proceed from fraud, mistake or negligence; for the insurer is thereby led into an error, and computes the risk upon false grounds.

As a representation is only matter of collateral information, it is sufficient if it be true in *substance*; and its not being inserted in the policy in the form of a warranty, is looked upon as a proof that the insurer does not require it to be strictly and literally true. Although the voyage be represented as being less than the voyage described in the policy, yet, if there be no fraud, and the voyage actually performed be within the policy, it will be protected by the policy. Even if a representation as to the course of the voyage be literally untrue, yet if it be made in conformity to an established usage of trade, and no person be deceived by it, and the voyage meant to be performed be within the policy, it will not avoid the contract.

Every representation respecting the state of the ship, and the time of her sailing, is material; and therefore if it be stated that a ship was *ready to sail* on a certain day, when, in fact, she had sailed the day before, this is both a misrepresentation and a concealment, and will avoid the policy.

Concealment, or "*suppressio veri*," is nearly allied to misrepresentation, or "*allegatio falsi*," and consists in the fraudulent suppression of any fact or circumstance material to the risk; and this, like every other fraud, avoids the contract *ab initio*, upon principles of natural justice. But it is not merely on the ground of *fraud* that a concealment avoids the contract; for even a concealment which is only the effect of accident, negligence, inadvertence, or mistake, will be equally fatal to the contract, as if it were intentional and fraudulent. Whatever respects the state of the ship, the time of her sailing, the nature of the employ in which she is to

be engaged, &c. ought to be fully disclosed; and the keeping back of any part of this fact will be fatal to the contract. In such case, the concealment so vitiates the policy that it will afford the insured no remedy, even for a loss arising from a cause unconnected with the fact or circumstance concealed; for a concealment is to be considered, not with reference to the event but to its effect, at the time of making the contract. A well-founded suspicion of concealment will amount in the courts to proof of fraud. As it is in some cases necessary to state to the under-writers the nature of the service in which the ship is to be employed; if this be attended with any extraordinary danger, the concealment of it will avoid the policy. A material concealment is fatal, though the fact concealed was not disclosed, because the broker thought it immaterial. Doubtful rumours respecting the safety of a ship which it is intended to insure "*lost or not lost*," ought to be faithfully disclosed to every under-writer; and the withholding of such information will avoid the contract. The obligation of a strict observance of good faith is equally binding on both parties in all contracts; and in that of insurance, the under-writer, as well as the insured, is bound to disclose all circumstances within his knowledge affecting the risk. If, therefore, it should appear, that at the time when he underwrote the policy, he knew that the ship was arrived safe, the contract will be void as to him, and an action will lie against him to recover back the premium.

There are, however, many matters, which are open to both parties, and upon which they may both exercise their judgments, with regard to which they may be innocently silent. The insured need not disclose what the under-writer knows, or what he ought to know. The under-writer needs not be told what lessens the risk agreed upon, and is understood to be comprised within the terms of the policy. He is bound to know every cause which may occasion natural perils, as the difficulty of the voyage, the variation of seasons, the probability of lightning, hurricanes, &c. He is also bound to know every cause which may occasion political perils, from the rupture of states, from war, and its various operations; and he is bound to know the probability of safety from the continuance and return of peace, from the imbecility of the enemy, the weakness of their counsels, or their want of strength. There are other circumstances which the under-writer ought to know; and, particularly, it is not necessary to communicate to him, that the ship is foreign built, though this enabled her to sail without convoy, and without a licence to do so, being within the exception in the stat. 38 Geo. III. c. 76. § 6; it being the business of the under-writer to obtain this information for himself. In cases of concealment, the question must always be, whether there was, under all the circumstances, at the time when the policy was underwritten, a full and fair statement, or a concealment: fraudulent, if designed; or, though not designed, varying materially the object of the policy, and changing the risk understood to be run; and in both cases avoiding the contract. It is not necessary that there should be any previous representation as to the state of the ship, that being covered by the implied warranty that she is sea-worthy. For a variety of other particular facts and documents, relating to the subjects of representation and concealment, we refer to Marshall's Treatise on the Law of Insurance, vol. i. b. 1. ch. 9 and 10. See WARRANTY.

REPRESENTATIVE, one that personates, or supplies the place of another; and is invested with his right and authority.

The word representative is equivalent to procurator or proxy.

The

The commons are the people's representatives in *parliament*; which see.

There is this defect in the constitution of our parliament; that whereas all Englishmen who have considerable estates ought not to be taxed without their own consent in parliament, by themselves, or their representatives; copyholders, of whom some have a thousand pounds a-year, have no voice in the election of knights of the shire. See PARLIAMENT.

REPRESENTATIVE *Character*, in *Political Economy*, thus denominated by way of excellence, or in contradistinction to other kinds of representation, constitutes the ambassador, or minister of the first rank, who represents his master in his very person and dignity. It places him above all other ministers, who are not invested with the same character, and precludes their entering into competition with the ambassador. (See EMBASSADOR.) Envoys are ministers of the second rank, and are not invested with the representative character, properly so called, or in the first degree. See ENVOY.

REPRESENTATIVE *Power*, in *Metaphysics*, a term introduced by Leibnitz, to signify that power of the human soul, by which it represents to itself the universe, according to the situation of the body in the universe.

Wolfius calls this power *vis representativa*, to denote its being an active power, or rather a force actually exerting itself. For he expressly says, *quod vis consistat in continuo agendi conatu*. And he thinks that from this principle of a *vis representativa*, every phenomenon of the human mind may be accounted for. See his *Psycholog. Ration. art. 529*.

But it may be presumed, that many will find this principle too obscure to be admitted.

When it is said, that our ideas are representative of things without us, or of the universe; it may be asked in what sense this is to be understood? Do they represent it, 1. As a picture does its original? Or, 2. As an effect of a cause? Or, 3. As a sign represents the thing signified? The first opinion is exploded in part by Locke and the Cartesians, and totally by Dr. Berkeley, late bishop of Cloyne. The second is admitted by Hobbes, but denied by Leibnitz himself and the idealists. The third should seem to be the opinion of Leibnitz, but he is not sufficiently explicit.

Dr. Berkeley admits ideas to be signs; but according to him they are arbitrary signs, depending on the immediate will of the Deity: hence the visual language; and ideas only signify or suggest each other, and spirits; but not bodies, the existence of which is totally unknown.

REPRIEVE, or REPRIVE, from *reprendre, to take back*, in *Law*, a suspending or deferring the execution of the law upon the prisoner for the present time.

A reprieve is properly a warrant from the king, for suspending the execution of a person condemned.

This may be, first, *ex arbitrio judicis*, either before or after judgment; as, where the judge is not satisfied with the verdict, or the evidence is suspicious, or the indictment insufficient, or he is doubtful, whether the offence be within clergy; or sometimes, if it be a small felony, or any favourable circumstances appear in the criminal's character, in order to give room to apply to the crown for either an absolute or conditional pardon. These arbitrary reprieves may be granted or taken off by the justices of gaol-delivery, although their session be finished, and their commission expired; but this rather by common usage than by strict right. (2 Hal. P. C. 412.) Reprieves may also be *ex necessitate legis*, as where a woman is capitally convicted, and pleads her pregnancy; which is referred to a *jury of matrons*. Another cause of regular reprieve is, if the offender become

non compos between the judgment and the award of execution. See LUNATIC.

REPRIMAND, a sharp authoritative reproof. Such a person was reprimanded in court by the bench, &c.

REPRIMAND, a military punishment at the head of a regiment, is sometimes ordered by a court-martial, and sometimes only in the presence of the officers of the corps: it is generally given by one of the field-officers, and usually in such terms as these: "Captain, or lieutenant A. B., you have been tried for —, and are, by the sentence of a general court-martial, found guilty thereof, and sentenced to be reprimanded at the head of the regiment: the disagreeable task of doing it is assigned to me: I therefore do hereby reprimand you, and hope, that it may prevent your falling again into the like error." Non-commission officers are sometimes, though not frequently, ordered to be reprimanded.

REPRISALS, or REPRIZALS, *Reprisalia*, in the *Civil Law*, a right which princes have to retake from their enemies such things as they unjustly detain from them; or other things equivalent to them.

The word is formed from the Italian *represaglia*, which signifies the same thing.

When a place is taken or held from a prince, he seizes another by way of reprisal. Sometimes he takes men of the opposite party, by right of reprisals.

The Romans called this *clarigatio*; and the Greeks had something like it under the name of *androlepsia*.

Reprisals are used between nation and nation, to do justice to themselves, when they cannot otherwise obtain it. If a nation has taken possession of what belongs to another; if it refuses to pay a debt, to repair an injury, or to make a just satisfaction; the other may seize what belongs to it, and apply it to its own advantage, till it has obtained what is due for interest and damage, or keep it as a pledge till full satisfaction has been made. The law of nations permits reprisals only upon a cause that is evidently just, as for a debt that is extremely clear. For he who forms a doubtful pretension, can at first demand only an equitable examination of his right. In the second place, he should, before he proceeds so far, have in vain demanded justice, or, at least, have the utmost reason to believe that it would be in vain for him to demand it. Then alone he may right himself. It would be too contrary to the peace, to the repose, and safety of nations, to their mutual commerce, and to the duties which bind them to each other, for any prince suddenly to apply to force, without knowing whether the other is disposed to do him justice, or to refuse it. It must be observed, in order perfectly to understand this article, that if, in a litigious affair, our adversary refuses the means of bringing the right to proof, or artfully eludes it; if he does not, with good faith, apply to pacific measures for terminating the difference; and, above all, if he is the first who begins acts of hostility, he renders the cause just, which was before doubtful: we may then make use of reprisals, or seize his effects, to oblige him to embrace the methods of reconciliation, which the law of nature prescribes. This is the last attempt before coming to an open war. As the wealth of the citizens forms a part of the total wealth of a nation, and between state and state, whatever is the property of the members is considered as belonging to the body, and is answerable for the debts of the body; it follows, that in reprisals they seize the goods of the subject, in the same manner as those of the state, or sovereign. Every thing that belongs to the nation is subject to reprisals, as soon as it can be seized, provided it be not a deposit trusted to the public faith. This deposit is found in our hands,

only

only in consequence of that confidence which the proprietor has put in our good faith; and it ought to be respected, even in cases of open war. Thus it has been usual to behave in France, England, and elsewhere, with respect to the money which foreigners have placed in the public funds. He, however, who makes use of reprisals against a nation, on the goods of its members indiscriminately, cannot be taxed with seizing the wealth of an innocent person for the debt of another; for, in this case, the sovereign is to recompense those of his subjects on whom the reprisals fall: this is a debt of the state or nation, of which each citizen ought only to support his quota. It belongs only to sovereigns to use and order reprisals, in the manner now stated. This is a measure of too great consequence to be abandoned to private persons. In all civilized states, a subject who thinks himself injured by a foreign nation has recourse to his sovereign, in order to obtain the permission of making reprisals. This is what is called desiring "letters of marque." See the next article.

We may use reprisals against a nation, not only for the actions of the sovereign, but also for those of his subjects. Accordingly the sovereign demands justice, or makes reprisals, not only for his own affairs, but also for those of his subjects, whom he ought to protect, and whose cause is that of the nation. But to grant reprisals against a nation, in favour of foreigners, is to set himself up as a judge between that nation and these foreigners, which no sovereign has a right to do.

As we may seize the things which belong to a nation, to oblige it to do justice, we may, for the same reason, arrest some of the citizens, and not release them till we have received entire satisfaction; the subjects thus detained being only regarded as a security to oblige a nation to do justice, if their sovereign is obstinate in refusing it. We cannot take away their lives, nor inflict any corporal pain upon them, for a refusal of which they are not guilty. But the sovereign may make use of force against those who resist the execution of this right, and use as much as is necessary to surmount their unjust resistance. In this case, the true and just welfare of the state is the grand rule: moderation is always laudable in itself; but the conductors of nations ought to exercise it only so far as it is consistent with the happiness and safety of their people. A sovereign, however, has no right to oppose force, or to make war against him, who, in such a case, by ordering the making of reprisals, only exercises his just right. Whenever a sovereign can, by the way of reprisals, procure a just recompence, or a proper satisfaction, he ought to make use of this method, which is less violent and less fatal than war. Those who run to arms, says the excellent Vattel, without necessity, are the scourges of the human race, barbarians, enemies to society, and rebels to the law of nature, or rather to the common father of mankind. There are cases, however, in which reprisals would be justly condemned, even when a declaration of war would not be so; and these are precisely those in which nations may with justice take up arms. When it relates to differences, not on an act of violence, or of an injury received, but of a contested right; after having in vain attempted ways of reconciliation, or pacific measures of obtaining justice, it is a declaration of war which ought to follow, and not pretended reprisals, which, in such a case, would only be real acts of hostility, without a declaration of war, and would be contrary to the public faith as well as to the mutual duties of nations.

There is one kind of retortion sometimes practised in war, under the name of reprisals, which we must here mention. If a general of the enemy has, without any just reason,

caused some prisoners to be hanged, a like number of his men, and of the same rank, will be hung up; signifying to him, that this retaliation will be continued for obliging him to observe the laws of war. It is a sad extremity thus to put a prisoner to death for his general's fault; and if this prisoner was before promised his life, reprisals cannot be made on him with any colour of justice. Yet as a prince, or his general, has a right of sacrificing the life of his enemies to his safety, and that of his men, if he is engaged with an inhuman enemy, who frequently commits such enormities, he appears to have a right of refusing life to some of the prisoners he may take, and of treating them as his were treated. But Scipio's generosity is rather to be imitated. That great man, having reduced some Spanish princes, who had revolted against the Romans, declared to them, that on a breach of their faith, he would not call the innocent hostages to an account, but themselves; and that he would not revenge it on a disarmed enemy, but on those who should be found in arms. (Liv. l. 28.) Alexander the Great, having cause of complaint against Darius for some malpractices, sent him word, that if he continued to make war in such a manner, he would pursue him to the utmost, and give no quarter. (Quint. Curt. l. iv. c. 1, and 11.) It is thus an enemy, violating the laws of war, is to be punished, and not by causing the penalty due to his crimes to fall on innocent victims. Vattel's Law of Nations, b. ii. ch. 18. b. iii. ch. 8.

REPRISALS is also used for a letter or permission, which a prince sometimes gives a subject, upon a full cognizance of the cause; authorizing him to retake from the first persons he meets of the opposite party, as many effects as make an equivalent to what have been violently forced from him, and for which the opposite prince has refused to do him justice.

These permissions are also called *letters of marque*, or *mart*; and in the stat. 27 Edw. III. *law of marque*; in regard a person denied justice in another man's territory, redresses himself by goods belonging to men of that territory. See *Letters of MARQUE*.

REPRISALS is also used in the same sense with recapture.

REPRISE, or REPRIZE, in the *Commerce by Sea*, a merchant-ship, which, having been taken by a corsair, privateer, or other enemy, is retaken or recovered by a vessel of the contrary party.

The word is French, and signifies a *resumption* or *re-taking*.

When a vessel, thus retaken, has been twenty four hours in the hands of the enemy, it is deemed a lawful prize. If the reprize has been made within twenty-four hours, the vessel is to be restored to the proprietor, with every thing in it, upon his allowing one-third to the vessel who made the reprize.

If the reprize has been abandoned by the enemy, either in a tempest, or from any other cause, before it have been led into any port, it is to be restored to the proprietor. See RECAPTURE.

REPRISE, in the *Manege*, is a lesson repeated, or a manege recommenced. Thus we say, to give breath to a horse upon the four corners of the volte with only one reprise, that is, all with one breath.

REPRISE, Fr., in *Music*. Every part of an air or strain that is to be repeated, without being written or printed twice over, is called by the French a reprise. There are various ways of marking repetitions in music: first by a double bar dotted; if on both sides, both parts or strains

are to be repeated; if only one side of the double bar is dotted, that side only is to be repeated. This sign §, and sometimes *da capo al segno* §, imply a repetition of particular portions of a melody; as do, likewise, dots in the spaces of the staff. (See RENOI and REFERENCE.) Gretry, in his Memoires, says that the repeating of the first and second parts or strains of a movement is a barbarous custom.

REPRISES, in *Law*, are deductions, drawbacks, or duties, paid yearly out of a manor, or lauds. Such are rent-charges, pensions, fees of stewards or bailiffs, &c. The manor of Doll yields 40*l.* per annum, *ultra reprizas*, besides all reprises.

REPROBATION, *REPROBATIO*, in *Theology*, a decree or resolve, which God has taken from all eternity to punish sinners, who shall die in impenitence.

Reprobation stands in direct opposition to *election*.

Divines hold it a symptom of reprobation, when a sinner is hardened so as not to feel any farther remorse or misgivings of conscience.

The casuists distinguish two kinds of reprobation, *positive* and *negative*. *Positive* is that by which God is supposed to create men with a positive and absolute resolution to damn them eternally. This opinion of reprobation is countenanced by St. Augustine, and others of the fathers; and is strongly maintained by Calvin, and most of his followers. Something like it is also found in the thirty-nine articles of the church of England; but it is now generally exploded, as injurious to the justice of God. *Negative* or *conditional* reprobation is that by which God, though he creates all men with a sincere desire to save them, and furnishes them with the necessary means thereto, so that all may be saved, if they will; yet sees there are several who will not do it, with the aids he shall afford them, how powerful soever; and sees, at the same time, they would do it with certain other aids, which he sees, but will not give them. *O altitudo!* &c.

By comparing one part of scripture with the other, says Dr. Doddridge in his "Lectures," (Prop. 142, schol. 1.) there seems to be this remarkable difference between the predestination to life and that to death (here called reprobation), that, in the former case, God determines by the influence of his grace to work such a change in the hearts of his elect, as that their salvation should on the whole be ascribed to him, and not unto themselves; whereas he determines to bring others into such circumstances, that though their ruin should in fact happen, yet they themselves should be the authors of it, and the blame lie as entirely upon themselves, as if it had not been so much as foreknown. (See Rom. ix. 22, 23. Matth. xxv. 34, 41.) But the opposers of this doctrine allege, that this kind of reasoning is an evasion and not a solution of the difficulty. This learned divine, adverting to the objection, that the above-stated doctrine tends to make the persons whom it concerns desperate, observes, that if it be granted, that *sufficient* assistances are given to *all*, none will have reason to despair, nor will any have an excuse to plead before God, in consequence of his secret purposes, which will not be made a rule of his final judgment. If it be said, that nevertheless those who are not predestinated to life are left under a necessity of perishing, and an impossibility of salvation; it must be owned, that it is difficult to say, how the doctrine, as explained by some, can be freed from this objection; but that this consequence does not necessarily follow from it, according to his state-

ment. See ELECTION and PREDESTINATION. See also SUBLAPSARIAN and SUPRALAPSARIAN.

REPRODUCTION, in *Physiology*. In speaking of the growth of organic bodies, we must notice their power of reproduction; that wonderful property of restoring or renewing parts that have been mutilated or entirely lost. This is one of the most important provisions of nature, inasmuch as it guards animals and plants against the multiplied dangers to which their bodies are exposed. Hence, when viewed in connection with the system of nutrition altogether, it forms one of those decisive and grand characters, which distinguish at once the machines that proceed from the hand of the Creator, from all, even the most ingenious and boasted, productions of human skill. The difference is recognised at the first glance; the distance is immeasurable. The springs and wheels of mechanical instruments have no power of repairing themselves, when they are bent, broken, worn, or spoiled; but such a faculty is enjoyed in various degrees by every animal and by every plant.

At different periods of the year, several organised beings lose, by a spontaneous and natural process, certain parts of their body, which are subsequently renewed. Examples of this occur in the fall of the stag's horns; in the moulting of birds; in the renewal of the cuticle of serpents, and other amphibia, of the larvæ of insects, and of the shell of the crustacea; the fall of the leaves of trees, &c. This may be called ordinary or natural reproduction. The stag's horn, or antler, as it should be more properly called, is a mass of true bone, possessing the structure and characters of osseous substances. In its early state it is soft, and traversed by large vessels, which must be reproduced every time the new horn is formed. This annual reproduction constitutes, in many points of view, one of the most remarkable phenomena of animal physiology. It affords a most striking proof, 1st, of the power of the nutritive process, and of the rapid growth, which is dependant on this in warm-blooded animals. For the horn of a stag, which may weigh a quarter of a hundred, is completely formed in ten weeks. 2dly. Of a limited duration of life in a part of an animal, entirely independent on the life of the whole animal, which in the stag extends to about thirty years. 3dly. Of change of calibre in particular vessels. For the branches of the external carotid, which supply the horn, are surprisingly dilated during its growth; and recover their former area, when that process has ceased. 4thly. Of a peculiar sympathy, which is manifested between the growth of the horns, and the generative functions. For castration, or any essential injury of the organs of generation, impedes the growth, alters the form, or interrupts the renewal of the horns. See the articles CERVUS, and HORN, in *Comparative Anatomy*.

The cuticle of the snake is separated every year, and comes off as a complete sheath, excepting the aperture, through which the animal escapes: the covering of the cornea is shed with the rest of the external integument.

Crustaceous animals (the crab, lobster, &c.) have a skeleton, which surrounds and contains their soft parts, and which serves, at the same time, the purposes of a skin. When it has attained its perfect consistence, it grows no more; but, as the soft parts still increase, the shell separates, and is detached, being succeeded by a larger one. The calcareous bodies in the stomachs of these animals, performing the office of teeth, are shed with the shell. See the article CANCER, in the account of the species *uricola*, and *ganmarus*.

The larvæ of insects cast their cuticular covering several times before their transformation. An interesting account of the

the particulars may be seen in the article ENTOMOLOGY, in the division "of the larva state," under the subdivision "lepidoptera."

The second, or extraordinary kind of reproductive power, is that by which wounds, fractures, or any accidental mutilation or loss of parts of an organized body, are remedied or restored. This exists in very different degrees in different departments of the animal kingdom. In man, and such animals as are nearly allied to him, the property is very limited, although sufficiently active to be capable of remedying the effects of great injuries. If a bone be broken, a muscle or tendon divided, or a piece of skin destroyed, processes are set up in the parts by which restoration is accomplished. The ends of the bone are joined by an osseous substance, which gives to the part its original solidity; the tendon regains its firmness and power of resistance; the muscle can contract again and move the points of its attachment; and the surface of the body is covered by a new piece of integument. The functions of the parts are restored; but the newly formed matter can be always distinguished from the original composition of the body, and possesses a weaker vitality. For, in some cases, old ulcers have broken out afresh, and even fractures have been divided in states of great general debility. A divided nerve is reunited, even if a small portion be removed: and the function of the part, suspended for a time, is thus restored. The case is different in the blood-vessels: the processes consequent on wounds of these tend to stop the hemorrhage, which in general can be effected only by the obliteration of the tube.

The power of repairing the effects of injury is modified by various circumstances. The health and strength of the individual, the age, the air, and other circumstances, which the surgeon must attend to, have great influence.

In the cases which have been just mentioned, the restorative power repairs injuries; but it goes no further. Neither in man, nor in any warm-blooded animals, are entire organs ever reproduced. If a limb be cut off, or a piece of flesh taken away, the wound is healed, the chasm is filled up; but the lost parts are never formed again.

In the lower orders of the animal kingdom, on the contrary, such are the strength and perfection of the reproductive energy, that considerable members are formed again, and we can hardly assign a limit to the power in some instances. The lower we descend in the scale of beings, the more surprising are the manifestations of this reproductive faculty. It is familiarly known, that the claws of the crab and lobster, and the entire limbs or tail of the newt, can be restored: the same holds good of the rays of the star-fish (asterias), and the arms or tentacula of the cuttle-fish. It was asserted by Bonnet and Spallanzani, that the entire head of the snail can be reproduced; but the assertion was suspected, because other experimentalists did not succeed in repeating the trials. Hence Blumenbach was led to observe, "that some experiments on this reproductive power require a hand exercised in such employments, together with various precautions, and a favourable combination of circumstances, for their success. Hence persons must be cautious in concluding against the truth of any statement, because their own experiments do not succeed. After several fruitless attempts on this subject, I have lately succeeded in observing the reproduction of the whole head of the snail (*helix pomatia*) with its four horns, which occupied about six months." Comparative Anatomy, translated by Lawrence, p. 219.

The same physiologist has given us a remarkable instance of reproduction in an animal of more complicated structure.

"I preserve," says he, "in spirits a large water newt (*lacerta palustris*), from which I extirpated nearly the whole eye several years ago: all the humours were discharged, and then four-fifths of the emptied coats were cut away. In the course of ten months an entirely new eye-ball was formed, with cornea, iris, crystalline lens, &c.; and this is only distinguished from the same organ on the opposite side by being smaller." Ibid.

Not only are amputated tentacula speedily replaced in the actinæ (sea anemones), but, if the animal be divided by a vertical or horizontal section into two halves, each of these becomes an entire actinia. See the article ANEMONE.

The fresh water polype exhibits very surprising powers in this way. If it be cut into two or more pieces, these become perfect animals. If it be slit half way down, the two halves are rendered perfect, remaining united below: these may be slit again with the same results. The opposite ends of two polypes may be made to grow together, &c. See POLYPE.

See the memoirs on animal re-productions in Spallanzani's tracts: also the works of Bonnet.

REPROOF, OBJURGATIO, in *Rhetoric*, is distinguished from *invective*; which see.

REPS, in *Geography*, a town of Transilvania; 16 miles N. of Fögaras.

REP-SILVER, money anciently paid by servile tenants to their lord, to be quit of the duty of reaping his corn.

REPTILES, in *Comparative Anatomy* and *Physiology*. Although the animals, whose structure we are about to explain, are perfectly similar to each other in their principal characters, and ought therefore to be united in one class, naturalists have experienced a real difficulty in discovering an appropriate name for the class. That of *amphibia*, employed by Linnæus and his disciples, although deduced from a striking circumstance in the economy of the more generally known reptiles, namely, the power of existing for a long time in water, as well as in air, is vague and uncertain in its signification. If we regard as amphibia those aquatic animals, which are able to live for some time on land, or those land animals, which can remain for a certain time under water, all animals are amphibious; for even the human subject and the mammalia can dive. If, on the other hand, the word amphibious be taken etymologically, and understood to denote an equal power of subsisting in air and water, it is applicable to no animals. Although reptiles can remain much longer under water than the mammalia, or birds, they are obliged, as their respiratory organs are only calculated for breathing air, to come sooner or later to the surface for this purpose; and they are drowned, like any warm-blooded animal, if detained in the water beyond that time. To enable an animal to exist equally in air and water, it should have lungs and gills; that is, it should have the power of breathing air, like the mammalia and birds, and of breathing water, like fishes; and it should be able to use either of these methods, to the exclusion of the other. But we know of no such animals. The larvæ of frogs and salamanders, the proteus anguinus, and the firen lacertina (see the latter part of this article), have indeed branchiæ and lungs; but as far as our knowledge hitherto goes, none of these could live out of the water. The lungs of the tadpole, and of the larvæ of salamanders, are designed for the service of those animals in their subsequent stage of existence; but do not give them the power of living in air: and the lungs, either of the proteus or firen, do not seem sufficient to enable them to dispense with the office of the branchial appendages. In its etymological sense, then, the term amphibious is not applicable to any animals we know of.

Linnæus

REPTILES.

Linnaeus places among his amphibia reptiles who never go into the water, and some fishes which never quit it. He could not fail to experience great difficulties in naming a class so ill conceived as that of his amphibia; consequently, this appellation is objectionable, as being vague and obscure; the genera comprehended in the Linnaean class amphibia, are too ill assorted to admit of their having a common name suitable to all. Daubenton divided them into two classes, naming one oviparous quadrupeds, and the other serpents. Lacépède adopted these two classes, and placed between them a third, that of oviparous bipeds. Hermann of Strasbourg, in his "Tabulae affinitatum Animalium," proposed to substitute, for the term amphibia, that of cryerozoa. "Si in novorum nominum impositione gloriam more multorum quaeremus, et ea re scientia promovetur, cryerozoa apte vocari posse putaremus, quia omnem fere naturam eorum animalium vox ista exhaustire videatur. *Κρυεροζοι* enim non modo frigidum, sed et horridum luridumque significat." Hermann, Tab. aff. Anim. p. 218.

Without entering further into the objections against the appellations just enumerated, we adopt that of reptiles, already employed by many modern naturalists, and particularly by Cuvier, in his "Tableau Élémentaire d'Histoire Naturelle." In fact, in the progression of the oviparous quadrupeds, as well as in that of serpents, the belly moves against the surface of bodies, over which they pass.

General Observations.—Referring to the article CLASSIFICATION for a view of the genera comprehended under these divisions, we prefix to the more detailed survey of the anatomy of reptiles, a short summary of the principal anatomical characters of the four orders into which the class is divided.

1. The CHELONIAN order; Testudines. Body inclosed in a bony shell. They resemble birds in having the masticating surfaces of their maxillary bones covered by strong cutting horny plates. Body supported on four limbs, terminated by a tail, and covered in almost all by scales. They copulate; fecundation takes place internally: the female lays eggs, covered by a firm calcareous shell: the young animals come out without incubation, merely by the heat of the atmosphere; and they undergo no metamorphosis. Stomach larger than in the other reptiles, and intestinal canal furnished with a caecum. The heart has two auricles.

2. SAURIAN order, or Lizard kind. They resemble the former very nearly in the structure of their principal internal organs. They have firm bones, like those of the mammalia: curved and long ribs, and a sternum. Teeth set in the jaw. The two branches of the lower jaw consolidated. A trachea composed of cartilaginous rings, an os hyoides and larynx, capable of producing sounds, at least in some individuals. Heart with two auricles. A simple penis in the male. There is a real internal copulation; the female lays separate eggs, generally covered with a firm shell, depositing them on dry ground, or in holes. The young ones come out of them, and undergo no metamorphosis. The skin is furnished with numerous plates or scales. Body elongated, and ending with a tail. Feet, often high, and strong enough to sustain the body above the ground in progression. Some are quadruped; others biped, having either fore or hind feet. Toes furnished with nails: generally five in number; but there may be four, three, two, and even one.

3. OPHIDIAN order; Serpents. They agree with the two former orders, in having firm bones, curved and long ribs, a larynx and trachea, capable of producing a slight hissing in moist. An external organ of generation in the male. A real internal copulation: the female lays eggs covered with a calcareous shell, which she deposits in holes filled with leaves,

under the roots of trees, in warm and rather moist situations. The young ones, when they quit the egg, are like their parents. They differ from the preceding orders, in having a long, eel-shaped, flexible body, covered with a skin, either furnished with scales or plates, or naked, unprovided with feet, and terminated by a tail, often very long. Numerous long curved ribs, not united together, as there is no sternum. The branches of the lower jaw not united in front. Upper jaw consisting of four branches. Simple, sharp, and numerous teeth; and long, curved, tubulated fangs, in addition to these, in the venomous kinds. They creep along the ground by undulations of their body. Excepting the ophisauri, they have no external auditory openings. Heart with a single auricle. Double penis. Eggs covered with soft calcareous shells.

4. BATRACIAN order; Frog kind. They resemble the preceding orders in having a tail; excepting the frogs and toads in their perfect state: a trachea and larynx, capable of producing sound. Like the chelonian and saurian reptiles, they have feet, and simple jaws, *i. e.* not formed of two branches, moveable on each other. In common with the saurian and ophidian orders, they possess teeth fixed in the jaws; and with the ophidian, a heart with a single auricle.

Many characters distinguish them from these three orders. Their naked skin, which is warty or tubercular, more or less moist, and nearly similar to that of the ceciliae, the last genus of the ophidian order. Softness of the bones; a sternum without ribs in the frogs and toads: rudiments of ribs and no proper sternum in the salamanders: true curved ribs surrounding the body in the proteus and firen. Four feet, or two only. They all swim; those with long hind legs and no tail leap; the tree-frogs attach themselves to leaves by the round tubercles of their toes: those with four equal limbs, or two only, crawl and swim, but do not leap. An external tympanum in the tree-frogs, frogs, and moist toads; no external ears in the others. No external organ of generation in the males, nor any internal real copulation. The female lays eggs in the water, or humid earth, and the male fecundates them as they pass out; or in the ovo-viviparous species, as the land salamander, the seminal liquor of the male is absorbed by the sexual organ of the female. The ova are without shells; from them proceed small animals, called tadpoles, which undergo various changes, before reaching their perfect state. They have branchiae in their tadpole condition, and thus approach to fishes.

Notwithstanding the obvious differences of organization in the different reptiles, as the turtle, lizard, serpent, frog, and salamander, we may remark that their structure does not deviate essentially in its general plan from that of the human subject. They have a bony vertebral column, and all the principal organs found in man, but with more or less striking modifications.

Reptiles have some relations, in their organization and habits, with other vertebral animals, particularly with fishes. This is seen in the true branchiae of the batracian larvæ and firen; in the scales of the skin in lizards and serpents; in the polygonal horny plates of the testudines, corresponding to those of some cartilaginous fishes; in the elongated form and habits of the firen, like those of the eel-shaped fishes.

The form of the body presents great differences in the reptiles; nearly all the chelonians, saurians, and batracians have four feet; and there are only two saurians with two feet. In the chelonians, the body is orbicular, more or less convex, inclosed in a bony case, and terminated by a small tail; the toes are separate and distinct in some, palmated and fin-like in others. All the saurians have an elongated body, covered with various kinds of scales, and terminated

by a very flexible tail, often composed of articulated rings. In the very elongated form of their body, the chalcides resemble serpents, though, in other respects, they are true saurians. The skin is quite naked in all the batracians; they have four feet; some have no tail, a stout, thick body, and the hind legs longer than the front; others have the shape of a lizard, being furnished with a tail, and having feet of equal length. Lastly, serpents have a very long, cylindrical body, covered with scales, and without limbs. These variations of figure must necessarily be attended with modifications in the form and position of organs; the internal arrangements will correspond with these outward signs.

Although the animals of this class differ very considerably in outward form, as well as in the general bulk of their bodies, they agree very nearly in the essential points of their organization, and more particularly in the functions of their animal economy. We may instance the mode of taking their food; the long abstinence of which they are capable; their oviparous generation; the length of time, for which they can bear an interruption of respiration; their tenacity of life and extraordinary power of reproduction; and the low temperature of their bodies. The last points, of animal heat and reproduction, two exceedingly interesting subjects of inquiry, which have been investigated of late years with great industry, form the most striking differences between cold and warm-blooded animals; the latter alone possessing that remarkable property of maintaining in themselves a temperature considerably exceeding that of the medium in which they live, while the former are distinguished by the wonderful extent of their power of extending or reproducing injured or lost parts.

An accurate knowledge of the structure of reptiles is not only important from its subserviency to the classic arrangements of natural history, and highly interesting from exposing to us new and rich scenes in the vast domains of nature, new forms of life, and fresh modifications of organization, accompanied with singular changes of functions already familiar to us in other shapes; but it acquires additional interest from the great use which physiologists have made of different reptiles in their experimental elucidations of the human economy. We must survey in a general view the structure and economy of these animals, and compare them with those of the warm-blooded classes, before we can determine how far the conclusions, drawn from experiments on reptiles, concerning the heart's motion, irritability, the action of the nerves, the effects of opium, &c. &c. can be transferred to the human body.

Organs concerned in the Vital Functions.—The mouth is situated at the extremity of the snout, and directed transversely. If we fancy the head to be divided by a horizontal cut, extending from before backwards, to its very posterior part, we shall have a just idea of the mouth of a reptile. The cranium is very small in this class, and the head consists almost entirely of the two jaws. The lower is articulated towards the back of the head, and thus allows the opening between the two mandibles, constituting the mouth, to be very considerable. Almost all reptiles swallow entire animals, and thus require this extensive opening. The margins of the aperture consist simply of the maxillary arches, which are not covered or enclosed by any thing deserving the name of lips. In no case is there any mastication; and the food or prey is taken by the teeth or tongue, so that a moveable covering of the jaws, similar to the lips and cheeks of the mammalia, is not necessary either for confining substances subjected to the action of teeth as organs of mastication, or for the purpose of reaching or seizing food.

The horny coverings of the mandibles, completely naked, and not concealed even by the smallest fold of skin, form the sides of the entrance into the mouth in the chelonian reptiles. Their food consists of marine vegetable productions, testacea, insects, &c. and does not require so large an opening for its introduction, as when considerable animals are swallowed whole. The mouth is consequently smaller in this than in either of the other orders; and does not extend completely to the back of the head.

The family of tortoises, which Geoffroy has called *trionyx*, offers a remarkable exception to what we have stated about the absence of lips: they have these folds, and a moveable proboscis at the end of the snout. "The existence of lips in these tortoises is an anomaly, the more likely to surprise us, inasmuch as the affinity of these reptiles to birds seems to assign a motive for the absence of lips, and also for the existence of the horny coverings of the mandibles." Geoffroy St. Hilaire, *Mem. sur les Tortues molles*; *Annales du Museum*, v. 14, pl. 1, p. 9.

In the saurians, the slit of the mouth goes to the very back of the head, far behind the ear. Its appearance is very formidable in the crocodile, where the hard strong jaws project into a large snout, and are armed with sharp powerful teeth, destitute even of gums: these jaws open to the very back of the head, and disclose a tremendous throat. The mouth is as large proportionally in the other saurians; but their size is too insignificant and their habits too harmless to allow of their inspiring that terror, which the formidable weapons of the crocodile so justly cause. The ophidians have not only a mouth equal in its transverse measurement to the diameter of their body; but they possess also the means of enlarging this aperture, so that they can swallow creatures whose diameter exceeds their own. The batracians have an opening as large as the size of the head will allow. In the latter, as well as in the ophidian, and most of the saurian reptiles, the integuments make a small fold at the edge of each jaw; these folds meet when the mouth is closed, so as to hide the edge of the jaws, but they possess no power of motion.

In the tadpole, in the proteus and firen, the mouth is much smaller than in the other reptiles; and they possess folds more deserving the name of lips. In the former there is a kind of horny apparatus within these lips, forming something like a beak. In the smallness of its mouth, and in these horny jaws, the tadpole is remarkably dissimilar to the perfect animal.

The Jaws.—In considering the jaws and their muscles, the teeth, and the tongue, we must bear in mind that these organs are calculated merely for seizing their food, and conveying it to the throat; in no case does the food undergo any mastication, as in the mammalia.

No reptiles have an upper jaw moveable on the head, like that of birds: the superior maxillary bones are in truth articulated moveably with the head in serpents, and may be extended and retracted, or moved laterally, as we shall describe presently; but, in general, the cranium and upper jaw are united into one piece, so far as their motions are concerned.

The most opposite opinions have prevailed respecting the crocodile, even down to the present time. Herodotus first observed, that it is the only animal possessing an upper jaw moveable on the lower, which remains fixed. The same opinion was generally held by the ancients, as Aristotle, Pliny, &c.; and several moderns speak in the same way, as Marcgrave, Marmol, Jacobæus, Vesalius, and the Jesuit Missionaries at Siam, who had opportunities of observing the living animal. But the anatomists of the Academy of Sciences

REPTILES.

Sciences (Perrault and Duverney) undertook to demonstrate the fallacy of the opinion of Herodotus. Geoffroy, one of the French savans, who attended the Egyptian army, has given us an account of the matter, which settles all these disputes, by proving that the statement of Herodotus is almost rigorously true; and that the crocodile is the only known animal, whose upper jaw, including within its branches the cranium, is moveable on the lower jaw, which possesses only an almost insensible degree of motion. "Nothing can be more paradoxical than the head of the crocodile: every thing which is placed laterally in other animals, as the moving powers of the jaw, &c. is thrown behind. The temporal bone itself extends backwards far behind the cranium, is elongated, and transformed into a double condyle. We have in fact nearly described the crocodile's head, when we say that it consists of two mandibles; for the cranium is so small, and out of place, that it escapes notice at first. We find it below, and a little in front of the occipital crista. The brain is so far forwards, that the eye and ear are above and a little behind it.

"The lower jaw is one-sixth longer than the upper, with the cranium: it presents a cavity with a double surface, in which the condyle of the temporal bone is articulated by ginglymus. The occipital condyle is in the same line as the temporal condyles: thus the head is really held at its articulations, like the lid of a box by the hinge, and is confined entirely to motions upwards and downwards. When a living or stuffed animal is examined, it is difficult to believe that the head ends at the extremities of the jaws. There is a regular fullness of the front of the neck, which might be regarded as the frontal part of the head: this arises from the enormous temporal muscles, which lie between the recti and obliqui. The latter, arising from the cervical vertebrae, and inserted in the occipital crista, elevate the head upon the neck, making it describe an arc of 45° . The skin behind the occiput being thin, yields to the motions of the head; while the lower jaw, on the contrary, is inclosed in a kind of sheath of hard, rugous skin. If there were a muscular force capable of drawing it down, this covering would impede its descent, while it is still further confined behind: the long process situated beyond its articular surface, describing a curve, approaches the skin exactly at the point where it is armed with a long scale, which offers an almost invincible resistance to the elevation of the condyle, and consequently to the depression of the jaw. Yet it is not entirely fixed, as Marmol imagined, who stated that it forms a single bone with the sternum. Two small muscles have the power of moving it slightly." (Annales du Muséum, tom. ii. p. 38, et seq.) This description is accompanied with an excellent figure of the skull, in the elevated state of the upper mandible. An analogous figure of the whole head is given by Humboldt, Recueil d'Obs. de Zool. & d'Anat. comparée, tom. i. pl. 4. From the figures of the Nilotic crocodile, in Blumenbach's *Abbildungen Natur Historischer gegenstände*, N^o 26; and of the St. Domingo crocodile, in the *Annales du Mus.* tom. ii. it appears, that the animal most frequently exhibits this elevation of the upper jaw. It cannot be necessary to point out how the raising of the entire cranium and superior mandible, just described, differs from the motion of the upper jaw upon the cranium: this has been already done by Blumenbach. See *System of Comparative Anatomy*, p. 111, note 8.

The length of the lower jaw is much more considerable in comparison to that of the upper in reptiles, where it is articulated far back, and is even prolonged beyond its articulation, than in mammalia and fishes, where this articulation is placed more forwards. Its composition is more compli-

cated in the reptiles, than in any other order. In the green turtle (*testudo mydas*) it consists of seven distinct pieces, a middle one forming the arch, and three others on each side, forming a continuation of its branches. The farthest of the three penetrates like a wedge between the two others, and forms a great part of the articular cavity. In many of the saurians the number is still greater: the lower jaw of the Nilotic crocodile, and of the caiman (*croc. americanus*), has no fewer than twelve pieces, arranged as follows. As the two branches are distinct, and united by a future, each of them must be composed of six pieces; 1, one, in which all the teeth are implanted; 2, another, lying along the internal surface of the former, without reaching to its anterior extremity; 3 and 4, two others articulated with the preceding; *viz.* an inferior one prolonged to the posterior extremity of each branch, a superior extending as far back as the other in the Nilotic crocodile, but not so far in the caiman. 5. The greatest part of the articular cavity is excavated in a fifth piece within the two former, and constituting the inner and superior part of the portion beyond that cavity. 6. Lastly, a sixth piece forms the front and inner part of the orifice of the dental canal. The lower jaw of the tupinambis (*lacerta monitor*) is also composed of twelve pieces, two of which form the coronoid processes, while the other ten are analogous to those described as entering into the formation of the lower jaw of crocodiles, excepting the last. There are eight or ten in most of the other saurians. We find four in each branch in the genus *anguis*; an anterior one united to its corresponding piece in front, and three posterior ones joined to the former. There are only four altogether in the amphibæna. The two last mentioned genera are the only ophidian reptiles, in which the jaws are not separated in front. In all the others there is a separation, and each branch has only two distinct pieces; an anterior, in which the teeth are implanted, and a posterior: they are united by future, and vary in relative length, according to the number of teeth. The very open arch, composing the lower jaw of the batracian order, is made up of six pieces; the middle of which are the most slender.

The anterior angle, formed by the union of the two branches, depends on the form of the snout in general, on the figure of the two branches, the presence or absence, number and size of the teeth, &c. It is rounded and very open in the chelonian reptiles, and more so in the batracian. In the ophidian order, which have the branches of the jaws moveable, it is susceptible of change, according as their extremities are approximated or drawn asunder; indeed in the former case only can it be properly said to exist at all. It is rounded in the amphibæna; more angular in the *anguis*; still very obtuse in the geckos (*lacerta gecko*), which have wide jaws, with the branches of the lower curved only in the horizontal direction; it is less so in the *cameleon* and *stellio* (*lacerta stellio*), the *scinks* (*lacerta scincus*), and the lizards, although in all these the two branches are only joined by their extremities. It is acute in the *tupinambis* and *iguana*, in which the branches, somewhat curved in the vertical direction, are approximated for a longer space. The Nilotic and Gangetic crocodiles differ very much in this respect. The two branches are united in the latter in the greatest part of their extent, as in the *cachalot*, and consequently form a long bill, in the edges of which the two rows of teeth are implanted. In the former, on the contrary, the branches remain separate, and only approximate towards their extremity, increasing a little in thickness at the symphysis.

The portion of the bone, which is incurvated towards the cranium in most of the mammalia, and constitutes

REPTILES.

the ascending branch of the jaw, does not exist in reptiles.

Motions of the Jaws.—Reptiles may be divided into two orders, according to the conformation of their maxillary bones, and the kind of motion of which they are susceptible. In the first would be placed those which have the lower jaw only moveable, as the lizards, the testudines (tortoise and turtle), the frogs, the salamanders, and the genera *anguis* and *amphisbæna* among the serpents. The second would include the colubres, and the venomous serpents, which can move both jaws.

The general disposition of the articulation is nearly the same in reptiles as in birds (see BIRDS, in *Comparative Anatomy*). Instead of a condyle at the posterior extremity of the jaw, an articular surface is excavated to receive an eminence bearing considerable analogy to the *os quadratum* of birds, and differing from it only in not being so moveable; often, indeed, it is only a simple prolongation of the temporal bone. To this most inferior point of the cranium, and to an articular surface nearly transverse in its direction, and shaped like a condyle, the lower jaw is articulated by a glenoid cavity, of which the middle part sometimes presents a rising line, converting it into a kind of pulley. Behind this articular cavity there is often a more or less considerable bony process, affording attachment to a muscle analogous to the digastric.

The most remarkable differences requiring our notice here are, the form of this prominence or condyle of the temporal bone; the greater or less prolongation of the process behind the articulation; the situation and extent of the temporal fossa; and, lastly, the existence or absence of the eminence occupying the situation of the coronoid process.

In proportion as the temporal eminence is carried backwards, the jaws approach more nearly to each other in their longitudinal direction. We see this in the crocodile, salamander, frog, turtle, and tortoise. When, on the contrary, it descends vertically, or very obliquely, and is very elongated, as in theameleon and iguana, it forms a kind of pedicle to the lower jaw, which, by separating it from the cranium, produces a much more considerable interval between the jaws. Several kinds of lizards, as the *lacerta agilis*, *draco*, &c. occupy the intermediate space between these two extremes.

The crocodile has the largest process for the attachment of the digastric. It is sensibly diminished in theameleon, the gecko, the tupinambis, and the testudines; and we see nothing of it in the pipa, the toad, frog, and salamander.

All four-footed reptiles have very deep temporal fossæ; they are united to the cavity of the orbit. In some species, the two cavities are separated in front by a bony circle, as in the testudines, the crocodile, the dragon, and the other lizards; but in the pipa, the frogs, and salamanders, there is no orbital circle.

There is, in the crocodile, a considerable excavation on each side of the cranium, behind the orbit, terminating below in the temporal fossa, and wanting in the crocodile with bony eyelid (*Crocod. palpebrosus*, Cuvier). It is bounded externally by a bone corresponding to the squamous portion of the temporal, which joins the lateral frontal bone, and thus forms a second kind of zygomatic arch. The size of this excavation differs much in the different species. No doubt it contains muscles. But we find no express and satisfactory description of it and its muscles, nor of the muscles of the jaw in the writings of the French naturalists already quoted, on the subject of the crocodiles.

The coronoid process of the lower jaw is not prominent in reptiles. There is a mere rudiment of it in the testudines,

theameleon, and some lizards, as the iguana, but there is no trace of it in the crocodile, the frogs, and salamanders.

The muscles of the jaw, in the oviparous quadrupeds, are analogous to those of the mammalia, and resemble them in number.

The masseter is large and distinct in the tupinambis, occupying all the space comprised between the posterior edge of the orbit and the meatus auditorius. It is directed obliquely from behind forwards, so that it raises and carries the jaw backwards. This muscle is small in the agame marbré (*lacerta marmorata*), and the turtle. It is so slender, that it can scarcely be distinguished from the lower part of the temporal.

The temporal muscle is very large in the turtle, occupying all the temporal fossa, and forming the back of the orbit. It is much smaller in the tupinambis and common lizard, in which it is almost entirely concealed by the masseter.

The pterygoidei are, in general, but imperfectly distinguished from each other. They envelope the whole branch of the jaw towards its extremity in the tupinambis; their fibres are in a manner twisted. They elevate the jaw and carry it forwards; thus they act in an opposite direction to the two preceding muscles. The same muscles are flat and thin in the turtle; their fibres are nearly transverse, so that they can move the lower jaw more directly from side to side.

In all these reptiles the muscle analogous to the digastric is flat and triangular; the broad portion is fixed to the cervical ligament behind the occiput, and the point terminates at the extremity of the jaw, behind its articulation, and near the pterygoid muscles.

After describing the muscles employed in moving the jaws of the turtle, Perrault asserts, in his "*Mémoires sur les Animaux*," that it has more power in its jaws than most other animals, that it can cut very hard and strong substances, and that the head of a small turtle has been seen, half an hour after it was cut off, to strike its jaws together with a noise like that of castagnettes. Daudin relates the following circumstance, communicated to him by a Dutch naturalist, who resided several years in India. "When we landed in Table bay, we took several hawk's-bill turtles (*testudo imbricata*), whose stomachs were filled with marine plants, and thick shells, which they easily break down with their horny gums. Three, which could not be brought on board, were tied to the trunk of a tree, with a thick cable, but when the sailors returned on the following morning, they found that these turtles had contrived to turn over on their bellies, and had then cut, with their gums, the cables with which they had been fastened." *Hist. Nat. des Réptiles*, in the edition of Buffon, by Sonnini, t. i. introduction, p. 38.

The two jaws are not moveable in all the serpents. They may be divided into three orders. 1. Those with the branches of the lower jaw consolidated, and consequently not possessing any power of thrusting forward the upper jaw, or moving it laterally. 2. Those with the branches distinct, and united in the recent state by an elastic ligament. There are two modifications of the latter; they may either have merely the power of separating the two jaws; or they may, at the same time, separate the jaws, and carry forwards a part, or the whole of the upper. We shall speak of the motions of the jaws according to this division, first describing the bones, and then the muscles.

The Bones.—In the serpents, with the lower jaw consolidated, the head is shaped nearly as in the lizards. This is the case in the *anguis* and *amphisbæna*, the *cæcilia*, *acorchordus*, and *hydrophis*. In the genus *anguis* the head very closely resembles that of the iguana. The arch of the upper jaw

REPTILES.

jaw is uninterrupted, and corresponds to the curve of the lower; the concavity of the palate is nearly complete in front. The palatine arches are directed backwards, and united to the condyloid pedicle of the temporal bone. This pedicle is short, and nearly vertical, and excavated behind for the attachment of the digastric muscle. The lower jaw has a small process behind its articulation for the attachment of the muscles, which depress it; and another towards its posterior third portion, analogous to the coronoid, for the elevating muscles.

In the amphibia, although the general configuration is a little changed, nearly the same arrangement is met with. The whole upper jaw is less separated from the cranium; the concavity of the palate is nearly complete. The palatine arches are much larger. The condyloid pedicle of the temporal bone, instead of being vertical, is continued nearly horizontally forwards. In proportion to the cranium, the lower jaw is much shorter; and it is articulated to the condyle by its posterior extremity. It is very wide behind, to produce the coronoid process. The orbit and temporal fossa are completely confounded; they are bounded by prominent bony cristæ, as in the carnivorous mammalia; hence, on first view, the head of an amphibia might be supposed to belong to one of the cheiroptera.

The serpents of the second kind, whose lower jaw is formed of two distinct branches, and in which the upper is capable of being separated, but not carried forwards, are all the non-venomous colubres, and the boas. The conformation of the upper jaw, in the latter, is very different from that of the lizards, although the bones are nearly the same, as we shall explain in the osteology of the head. The ossa incisiva are not always furnished with teeth; sometimes even, as in the boas, they do not unite the superior maxillary bones. All the other bones of the jaw are moveable on the cranium, which serves merely as a point of support.

The superior maxillary bones are two long branches, in which the teeth are implanted; they form the outer edge of the palate. They are articulated by two points; first towards their middle, as a lever of the first kind, on a small bone analogous to the os malæ, and forming the anterior edge of the orbit: nearly at the same point, but towards the inner side, the superior maxillary bone has a process, which slides in a groove, and rests on the palatine arch. It moves on these two surfaces, playing backwards and forwards. The anterior extremity of this upper maxillary bone is free: the posterior receives the end of a particular bone, serving to unite it to the palatine arches.

The palatine arches are the two internal bony branches themselves, formed of two parts. An anterior, which is free in front, and articulated by three points; behind, with a bony branch, which proceeds towards the extremity of the lower jaw within its articulation, and appears to form a continuation of it; on the outside, with a particular bone, uniting it to the maxillary arch; and above, with the basis of the cranium, in front of the orbits. The posterior portion of the palatine arch is analogous to the pterygoid alæ or laminae. It is articulated by three points; 1st, in front, with the posterior extremity of the first portion; 2d, behind, with the lower jaw towards the inside; 3d, on the outside, and towards its anterior part, with the bone uniting it to the maxillary arch. Lastly, the third palato-maxillary is a piece nearly cylindrical in its middle, flattened and widened at its two extremities, by which it is supported, being articulated, on the outside, to the posterior extremity of the maxillary arch, on the inside, towards the middle and outside of the pterygoid portion of the palatine arch.

In consequence of this singular formation, the whole upper jaw is, as it were, suspended and distinct from the cranium, and influenced by the motions of the lower jaw. When the posterior extremities of the latter are separated, the pterygoid arches are moved apart. They carry with them the posterior extremities of the palatine and maxillary arches, while at the same time the anterior extremity is moved inwards. On the contrary, when the two internal edges of the pterygoid laminae are brought together, or, what is the same, when the articular extremities of the lower jaw tend to approximate, the anterior ends of the palatine and maxillary arches are carried outwards, and separate from each other.

The serpents of the third order, which have jaws susceptible of separation, and which at the same time can carry forwards the superior maxillary bones, properly so called, exhibit but a slight modification of the structure described as belonging to the preceding division. Their pterygoid arches are articulated with the lower jaw, towards its extremity, on the guttural aspect. They also receive the bone which is to join them to the palatine arches; but the latter are very short, directed forwards, and only containing venomous teeth. This intermediate bone, therefore, goes above the superior maxillary, which is itself articulated in the front of the orbit, or the short and moveable cheek-bone. When the lower jaw is moved forwards, the palatine arch, carried in the same direction, drives before it the bone which joins it to the maxillary. The latter, extremely moveable, is immediately turned up, or carried forwards, by moving on the cheek-bone, which causes a complicated series of motions.

The articulation of the lower jaw is the same in the whole family. The temporal processes are prolonged posteriorly: they receive an intermediate bone; analogous to that designated by the name quadratum in birds. This bone is very short, and possesses little motion, in the species which have the upper jaw fixed, and the inferior consolidated.

It is directed forwards in the amphibia towards the lower jaw, which is shorter than the cranium by nearly one-third;—a circumstance which belongs only to this species. In the anguis, the os quadratum descends much more obliquely forwards.

In all the other species the bone last-mentioned is much longer. It sometimes descends perpendicularly, as in the boas; but it is commonly directed backwards, as in most of the colubres. The temporal extremity is generally widened and excavated by a small depression. The inferior extremity is rounded like a condyle, and received into an excavation of the posterior extremity of the corresponding branch of the inferior maxillary bone.

From the nature of its articulation, the lower jaw of either side is not only susceptible of elevation and depression, so as to open and shut the mouth, by playing on the os quadratum, as is the case only in the genera amphibia and anguis; but it may also be carried outwards, and take with it the os quadratum, as is the case in the colubres and venomous serpents, whenever the pterygoid arch is moved outwards. That is to say, whenever the upper jaw is widened, the inferior must follow its dilatation, because the posterior extremities of the pterygoid arches, being articulated with the internal part of the lower jaw, it must move together with them. The arrangement of the muscles accords very well with this formation, as we shall proceed to describe.

Muscles of the Jaws.—The maxillary muscles of the genera anguis and amphibia, and probably of all the serpents with a consolidated under jaw, resemble those of the common

REPTILES.

common lizard: but they are very different in those whose lower jaw consists of two distinct pieces: we shall describe them in the rattlesnake.

Here the muscles of the lower jaw are concealed in the lips, and go round the mouth on each side. That which forms the anterior edge of the commissure of the lips is the strongest, and seems to hold the place of the masseter. It arises by firm aponeuroses from the tendinous sheath, which contains the venomous gland. Its fibres form a considerable cord, which constitutes the whole thickness of the lower lip, and are inserted in the upper edge of the inferior maxillary branch for almost two-thirds of its length.

The muscle immediately behind is analogous to the temporal, and is much slenderer than the preceding. It is a muscular fasciculus, of which the superior extremity is fixed to the temporal excavation behind the orbit, and the inferior, after going backwards behind the commissure, is confounded with the insertion of the last muscle. It is obvious that the contraction of these two muscles must approximate the jaws, and thus close the mouth.

In the commissure of the lips, and behind the two last muscles, we see another resembling them in form, but much shorter. It occupies the inferior part of the os quadratum, and about the posterior third of the jaw, at the outer edge of the dental canal. It is an accessory muscle to the temporal and masseter.

The muscle corresponding to the digastricus occupies the whole length of the back of the os quadratum, and terminates at the posterior apophysis of the maxillary branch beyond and behind its articulation.

The muscles moving the upper jaw are more numerous. One arises, by aponeurotic fibres, from the capsule of the joint, between the maxillary branch and the os quadratum, and passes forwards and upwards towards the sheath of the venomous teeth, being partly expended on that sheath, and on the posterior apophysis of the superior maxillary bone. Its use is evidently to draw down the venomous teeth, when they have been elevated.

Two other muscles act on the pterygoid and palatine branches. Both are situated between the middle line of the basis cranii and the palatine arches. The lower, situated immediately under the skin in the palatine fossa, is a plane of elongated fibres, occupying the whole middle line of the cranium, and going backwards to the internal surface of the bony pterygoid plate, which it will carry inwards and forwards, so as to protrude the superior maxillary bone, and elevate the venomous fangs, at the same time contracting the mouth by the approximation of the two internal arches.

The other muscle, slenderer, and placed above the preceding, towards the basis of the skull, extends from the anterior portion of the palatine arch, and the whole length of this arch, to the middle of the basis cranii, crossing the direction of the last muscle, on which it is placed. When it contracts, it carries backwards the whole mass of the upper jaw, at the same time approximating its two branches.

By means of this mechanism, serpents can twist their mouths in seizing objects, and dilate them extraordinarily, so as to swallow animals larger than themselves. Their teeth serve merely for holding their prey; and the muscles moving the bones, in which these teeth are implanted, cannot move them in such a way as would be necessary for mastication, but merely depress, elevate, approximate, separate, protract, and retract them.

Lacépède thus describes the motions of the jaws in serpents. "While the teeth of one side are fixed in the prey which the animal has seized, and are therefore motionless,

those of the other side are carried forwards, penetrate the animal, drag it towards the throat, and there fix it in their turn; when the opposite ones are again advanced to repeat the same process on their side. By these repeated alternate motions of the two sides of the jaws, combined with their lateral expansion, serpents are enabled gradually to swallow animals of a diameter exceeding their own." Hist. Nat. des Serpens.

The Teeth.—Their structure has nothing peculiar in reptiles. The bone is compact and hard; the enamel thin; and, as they are always thin, there is none of the third substance called by Cuvier the cement. We are not acquainted with any facts concerning the succession of the teeth in reptiles;—whether they have two sets, or that the first grow constantly, or that the jaws are elongated anteriorly, &c. The crocodile forms an exception to this remark: we are indebted to Cuvier for a very interesting account of the succession of their teeth, which we shall state presently.

The chelonian reptiles, like birds, have no teeth, properly so called: the horny substance encasing their jaws, and supplying the place of teeth, will be described at the end of this account of the teeth of reptiles.

The saurian, ophidian, and batracian reptiles may be compared to the cetacea; as they do not masticate their prey, the teeth are calculated merely to hold, and not to divide it: hence they have much less influence on their economy than those of viviparous quadrupeds. They accord, however, tolerably with the natural genera and subgenera.

They are almost always the same in all parts of the jaw, so that they admit of division into different classes, according to their configuration, only in very few species.

Sometimes they are attached to the two jaws only, as in the mammalia: this is the case with the saurians (excepting only the iguana, which has palatine as well as maxillary teeth); sometimes they are implanted also in the palate, as in the ophidians, with the single exception of the amphibæna. Their number is of less importance; first, because it is considerable, and not accurately determined; secondly, because they fall out without any hitherto ascertained regularity, either in situation or time.

Teeth of the Saurians.—In the crocodile the enamel is more or less striated longitudinally. The upper and lower teeth cross when the jaws are shut. They are all conical, hollow, generally a little curved, and marked with two longitudinal projecting lines; an anterior and a posterior one. The five or six posterior teeth on each side are more obtuse and compressed than the others.

In a living crocodile, which Perrault observed at Versailles in 1681, he found that all the teeth were slightly bent towards the throat, and that this curvature was the most conspicuous in those near the end of the snout. When the jaws were drawn together, the teeth of each jaw passed into the intervals between those of the other, so that an uninterrupted series was visible, as there are no lips to hide them. He says further, that the points of the upper teeth entered into excavations of the lower jaw.

The following account is derived from Cuvier's *Obs. sur l'Osteologie des Crocodiles vivans*, in the 10th volume of the *Ann. du Mus.* "The number of the teeth does not change with the age of the animal: a crocodile quitting the egg has the same number as one twenty feet long. I have ascertained this fact in a series of heads from an inch to two feet long. The back teeth may be a little concealed by the skin of the gums. The interior is always hollow, although

REPTILES.

although the teeth, as in all other cases, are formed by successive strata.

“ The capsule containing the new tooth is not enclosed in a separate cell of the maxillary bone, as in the mammalia, but it lies in the bottom of the socket of the tooth which it is designed to succeed. This little shell is first on the internal surface of the root of the tooth in place; it occasions a groove in this part, by which, as it increases in length, it penetrates into the hollow of the latter, and then destroys by its pressure the pulp that filled its cavity, and furnished the materials of its increase. Hence, at whatever age we may remove a crocodile's teeth, we shall find, either in the alveolus, or in the cavity of the tooth itself, a small tooth, either in the form of a thin and short shell, or more advanced and ready to occupy its place, when the old and enveloping tooth shall have been discharged. This succession seems to be repeated as long as the animal lives: hence the teeth always appear sharp and fresh, and although larger, they are not much more worn in old than in young crocodiles. I have ascertained all these facts in a recent head, and in others preserved in spirits of wine: and I could distinguish very clearly pulps and capsules similar to those of quadrupeds.

“ This process was tolerably well understood by Perault and Duverney; Mem. pour servir à l'Histoire des Animaux, v. iii. p. 167.

“ As the teeth of the crocodiles are generally nearly perfect cones, and enlarge to their very basis, how can they come out of the alveoli, of which the entrance is much narrower than their base? The new tooth, as it is developed and fills the cavity of the old, compresses its substance against the socket, destroys its consistence, makes it crack, and thus disposes it to be separated on the slightest shock at the level of the gum. The fragments are easily thrust out of the sockets. We often find in the sockets of crocodiles, when changing their teeth, rings formed by the relics of the old teeth left behind, through which the new are making their way: and such are also found in the fossil jaws of true crocodiles.

“ The base of the cone is generally not entire, but exhibits a more or less deep fissure on its internal side: it has been already mentioned that this is caused by the pressure of the germ of the new tooth. While the germ is very small, this fissure does not exist, and the germ itself never exhibits it.

“ Although the teeth may be said to be all alike, and arranged in an uniform series, some are rather larger than the rest; and the greater this inequality, the more irregular is the line of the jaws.

“ These larger teeth are either received into grooves of the opposite jaw, or into holes, or they perforate it completely.

“ In the caimans or alligators, the first of Cuvier's subgenera, (containing the American species,) there are from nineteen to twenty-two teeth on each side below, and nineteen or twenty above. The two first of the lower jaw penetrate at a certain age the front of the upper jaw, and go completely through it. The fourth of the same jaw are the longest, and go into the holes of the upper jaw, in which they are entirely concealed when the mouth is shut. The five front in the upper jaw are intermaxillary teeth.

“ The first and fourth of the lower jaw are long in all the three subgenera; next to these come the eighth and ninth of the upper, the eleventh of the lower jaw in the true crocodiles and caimans. The caiman with bony eye-lids (*Crocodylus palpebrofus*) has the twelfth below and the tenth

above the longest. After the fourth in the gavials (*Longirostres*) they are all nearly equal, so that the jaws in these have not so waving a line as in the other subgenera.

“ The fourth tooth below might be called canine, from its superior length, and because it corresponds to the future between the maxillary and intermaxillary portion of the upper jaw.

“ In the second sub-genus, or proper crocodiles, there are fifteen teeth on each side below, and nineteen above. The first of the lower jaw penetrate the upper; the fourth pass into grooves, and are not lodged in cavities of the upper jaw.

“ The gavials (*longirostres*) have 25—27 on each side below, and 27—28 above. The two first and the two fourth of the lower pass into grooves, not into perforations or cavities of the upper.”

In the tupinambis of the Nile we find sixteen above, of which five are intermaxillary, thirteen below; all conical, and slightly bent backwards: the posterior are the largest and most obtuse. In a tupinambis from the Moluccas there were six above, and seven below, all compressed and pointed.

The teeth of the common lizard, the iguana, and agame, are cutting, and more or less serrated on the edges; they are all so in the iguana, where several have six or eight denticulations, and there are twenty or twenty-one teeth on each side. The common lizard has twenty-one or twenty-two, but the anterior are not sensibly denticulated, and the others have merely a groove. The agame has nineteen or twenty, all with three denticulations. In these three genera they increase in size from before backwards.

They are triangular, with a little groove before and behind, in the stellio: there are sixteen or seventeen such on each side, and two large conical canine teeth. There are, moreover, two small conical intermaxillary teeth above, to which nothing corresponds below.

The dragon corresponds to the stellio in its teeth, except that the canine are proportionally longer than the incisors: the number is the same. There is a good representation of them in Blumenbach, *Abbildungen Natur-Historischer Gegenstände*, No. 98.

The gecko has thirty-five or thirty-six teeth on each side, all of equal size, close, simple, slender, and pointed. The flat-headed gecko has seventy or seventy-four on each side. There are twenty-two on each side, above and below, in the scink, all conical, short, closely set, and of equal size.

The camelion has, on each side, eighteen above and nineteen below; of which the anterior are very fine, the posterior much larger, and furnished with three points.

Teeth of the Batracians.—All these have teeth in the palate; as to the jaws, the salamanders have them in both, the frogs in the superior only, and the toads in neither.

The palatine teeth form, in the toads and frogs, a transverse line, interrupted in the middle. They are implanted in the palate bones. They form two long parallel lines in the salamander.

The maxillary teeth are small, pointed, and closely set. The frog has about forty on each side above, eight of which are intermaxillary; the salamander sixty, both above and below, and thirty on each side of the palate.

Teeth of the Ophidians.—The serpents are divided first into two families, those which can, and those which cannot, separate the two halves of the upper jaw. The former have no incisor teeth; but they have palatine, maxillary, and mandibular,

REPTILES.

mandibular, or teeth of the lower jaw. The latter, having all the edge of the upper jaw furnished with teeth, possess, consequently, a kind of incisors.

The second family includes only the angues and amphibæna. The former, besides the conical slightly curved teeth of uniform size, which they have in both jaws (eighteen or twenty above, and fifteen or sixteen below on each side), possess others, very small and short, arranged in two rows, on the posterior half of each palatine arch.

The other family is subdivided into two tribes, the venomous and the non-venomous. In the latter there are conical,

curved, and very pointed teeth, directed backwards along each maxillary, palatine, and mandibular arch; consequently there are four rows in the upper, and two in the lower jaw, all nearly longitudinal.

On the maxillary branch of the venomous serpents there are only the hollow fangs, attached to the anterior extremity only; consequently, with the exception of these fangs, there are only the two palatine rows above, and the two rows of the lower jaw below.

The following is a table of the numbers of teeth on each side in some species.

Names.	Incisor Teeth.	Maxillary.	Palatine.	Mandibular.
<i>Boa constrictor</i> .	2	18	14	
<i>Coluber molurus</i> .	0	18	24	20
<i>Coluber natrix</i> .	0	16 of which the anterior are the largest.	25 of uniform size; very small.	18 the anterior largest.
<i>Coluber natrix</i> (common snake).	0	18 the posterior largest.	28	24
Rattlesnake (<i>crotalus horridus</i>).	0	1 and several rudiments not fixed.	14	5 or 6
<i>Coluber haje</i> .	0	the same.	25 and a parallel row of small ones.	12—14
<i>Coluber naja</i> .	0	the same.	the same.	
<i>Anguis fragilis</i> (blindworm).				
<i>Amphibæna fuliginosa</i> .	3 on each side, and a middle one.	5	0	8

To this table, which is derived from the *Leçons d'Anat.* comp. of Cuvier, we add a second, drawn up by Palisot Beauvois, a French naturalist, who spent many years in

America, and whose observations on serpents are inserted by Daudin in the fifth volume of his *Natural History of Reptiles*.

REPTILES.

Comparative Table of the Teeth of several Serpents of North America, by Palifot Beauvois.

Names of the Species.	Upper Jaw.			Lower Jaw on each Side.	Total Number of Teeth.	Food.
	External Branch.		Internal Branch on each Side.			
	Fangs on each Side.	Common Teeth on each Side.				
<i>Crotalus durissus</i> .	1	0	6	5	24	Squirrels, various birds, rats, mice.
<i>Cr. rhombifer</i> .	1	0				Hares, squirrels, birds, rats, mice.
<i>Cr. miliaris</i> .	1	0				Grafshoppers and other insects, worms.
<i>Vipera berus</i> .	1	0	10	10—12	44—48	
<i>Coluber heterodon</i> (hognose-snake).	0	13 the two lower ones three times larger.	14	12—15	80—86	Insects, worms, field-mice, shrews.
<i>Col. erythrogrammus</i> .	0	10	15—16	10—12	70—76	Birds, young turtles, frogs, salamanders, the amphibious rat.
<i>Col. constrictor</i> .	0	12	28—30	16—18	112—120	As the last; also squirrels, lizards, tree-frogs.
<i>Col. getulus</i> (chain snake).	0	8	18—20	10—12	72—80	Lizards, a serpent with red and black bands, col. fulvius?
<i>Col. fasciatus</i> .	0	8	20—24	12—15	80—94	Small fishes, frogs, insects, worms.
<i>Col. fulvius</i> .		the teeth not ascertained.				Grafshoppers and other insects.
<i>Col. saurita</i> .		the same.				Tree-frogs, insects, worms.

Venomous Teeth and Gland.—We have stated that the innocent serpents have teeth along the maxillary edge of the upper jaw, and in the palate; that is, four parallel rows, two external or maxillary, two internal or palatine. The venomous kinds, instead of the maxillary rows, have the venomous fangs at the anterior end of each superior maxillary branch; and they possess the palatine rows, as well as the innocent serpents. There is no difference in the teeth of the lower jaw. The venomous fangs are much longer and thicker than the other teeth: they are conical, sharp-pointed, and perforated by a fine tube. They are moveable at the will of the animal, and can be drawn up from the jaw, or laid down at pleasure. They are contained in a kind of cavity formed in the gums, from which their point projects.

At the end of his account of Indian serpents, Ruffel has given two finely engraved plates, representing the appearances of the teeth in the venomous and innocent species. In the *coluber catenularis* (tar-tuttah), an innocent serpent, there are two marginal or maxillary rows of simple teeth, and two palatine rows. The *vipera elegans* (katukah-rekula-podah) has also two palatine, but no marginal or

maxillary rows. The teeth are surrounded by a fringed membranous covering, which almost conceals them. The points alone appear, when the membrane is not entirely depressed. At the anterior end of the maxillary bone, on each side, is a large membranous sac, wrinkled, and containing the fangs. The *vipera naja*, or spectacle snake, has the palatine teeth, and two venomous fangs, like the last; but the teeth are smaller, the fangs shorter, and the membranous sac less apparent. The *bungarus-pamah*, a species of *bungarus*, has the palatine teeth, two fangs still smaller than in the spectacle snake, and at the edge of the mouth, behind the orifice of the bag inclosing the fangs, three small teeth on each side, which may be considered as an imperfect maxillary row.

In the *vipera elegans*, the fang is fixed to a bony basis, which is attached to the superior maxillary bone: this basis is much longer in the spectacle snake, and has attached to it the three small simple teeth already mentioned.

Behind the venomous fangs in the vipers and other serpents, are other smaller fangs, said to be designed to replace the former when they are lost.

Blumenbach has given an excellent delineation of the mouths

REPTILES.

mouths of the *boa constrictor* and the *crotalus horridus*, in his *Abbildungen Natur-Historischer gegenstände*, No. 37, to shew the difference between the venomous and innocent kinds; an object of the greatest importance, both with regard to the fewer species of the former, and the much more numerous of the latter kind, in order to warn mankind against real danger, and preserve them from groundless terrors. "All serpents (says Blumenbach), whether venomous or not, have the double internal row of palatine teeth, and the inferior maxillary teeth, in common. But the innocent species have moreover the whole outer edge of the upper jaw furnished with teeth: in the venomous kinds, this is toothless. But the latter have, at each anterior corner of the mouth, attached to the upper jaw, the long hollow fangs with a slit at their point. These are connected with the venomous glands, of which they may be regarded as bony excretory ducts, to convey venom into the wound made by the bite.

"When, therefore, we see in any snake four rows of teeth in the upper jaw, *viz.* besides the two internal palatine rows, an external row on each side running to the corner of the mouth; we may be sure that the species is poisonous, and so far innocent."

The *poisonous gland*, peculiar to the serpents with fangs, and said to be of the conglomerate kind, like the salivary glands of the mammalia, is situated on each side, behind the orbit, close to the branch of the superior maxilla, and almost immediately under the skin. It is covered by a membranous or aponeurotic semitransparent sheath, fixed to the bones of the head in front of the gland. The excretory duct extends from the anterior part of the gland, immediately under the orbit, to the bony basis of the fang, and opens into a canal excavated in the fang, running through it from above downwards, and terminating by an oblique aperture on its anterior surface. Two muscles destined to elevate the fangs, to depress the superior maxillary bones, and consequently to close the mouth, pass along these bones from before backwards; one on the outer, and the other on the inferior side of the gland. These cannot act without compressing the gland, and expelling its secretion into the excretory duct. See a representation of the gland and the surrounding muscles in the *coluber naja*, *Phil. Trans.* 1804, pt. 2. pl. 8.

In the article *Poison* of this work, there is an account of the appearance and sensible properties of the fluid secreted by the venomous gland of the viper, and of its effects on animals. We have a few additional points to mention on this subject, as well as concerning the poisonous properties of some other serpents.

Fontana asserts, that the noxious qualities of the secretion are retained for a long time, even in a dry state; and that persons have suffered from wounds inflicted by the fangs of vipers, and other venomous serpents, preserved in spirits or dried, even years after the death of the animal. The venom retains its colour and transparency in the dead tooth, and is still active enough to kill animals, if it be rendered fluid by immersion in warm water. He also found it active after many months, when dried and powdered.

Leeches, snails, and slugs, were not injured by the venom of the viper. The blindworm and common snake were not affected. Of tortoises, some were insensible to the bite, others died at the end of some hours, when bitten by several vipers.

The bites of the vipers of these climates produce more or less alarming symptoms in the human subject, but are not attended with danger. A peasant, bitten by a viper in the little toe, had the foot, leg, and thigh swollen in six hours; the pulse small and intermittent; there was head-ache, pain in

the abdomen, lassitude, and oppression; he cried frequently and had no appetite. He gradually recovered in two days, under the use of vegetable decoctions and poultices, which probably did not contribute much to his restoration. Daudin, *Hist. Nat. des Reptiles*, 8vo. introd. p. 138.

Lepéchin mentions the circumstance of a young *Baschkir*, ten years old, being bitten by a black viper (*coluber prester*, L.) in the foot. "Son pied enfla extrêmement en moins d'une demi-heure, et il éprouvoit tant de douleur dans la partie blessée, qu'il ne pouvoit pas remuer le pied sans être forcé de crier: la pâleur extrême de son visage, ses yeux troublés, et sa respiration gênée, annonçoient très-fortement le danger que couroit ce jeune homme, si l'on n'y apportoit un prompt remède." Olive oil externally, and volatile alkali by the mouth, were the successful remedies. Daudin, v. 6. p. 168; (quoted from Lepéchin, *Tagebuch einer Reise*, &c. t. 2. p. 105).

While Charas was engaged in researches for his work on the viper, he was bitten in the fore-finger. He immediately sucked the wound, made a ligature on the root of the finger, and another on the wrist. The bite gave him but little pain. He took some sudorifics, which operated in a few hours, and he was cured.

Boyle says that he cured a man bitten by a viper, by holding a red-hot iron near the wound for a quarter of an hour. The truth seems to be, that the effects of the bite are not considerable in the human subject; and this accounts better for the recovery of persons bitten, than any virtues in the remedies employed.

The wounds inflicted by these animals are not, however, always so free from danger. The viper *chersea* (*coluber chersea*, L.), says Daudin, is very venomous, and its bite is often mortal. Linnæus employed olive oil in the case of a woman who had been bitten; but she died, although the remedy had been successfully employed in the bite of the black viper (*vipera prester*). Daudin, v. 6. p. 148.

The wounds of many Indian, African, and American serpents, are, however, fatal to the human subject. The *vipera cornuta* of southern Africa, is described by Paterfon as very virulent, inasmuch, that the *Bosjesmen* and *Namaquaws* employ its venom for poisoning their arrows. Daudin, *ibid.* p. 189.

A captain Hall made some experiments on the poisonous powers of the rattlesnake, of which he has recorded the results in the *Philosophical Transactions*. The first dog bitten by this animal died in fifteen seconds; the second at the end of two hours; and the third of three hours. He recommenced his experiments with the same serpent on the following day: the first dog died in thirty seconds; another in four minutes. Three days after, a frog died in two minutes, a chicken in three minutes. A little time after, an *amphibæna* was bitten, and died in eight minutes; and the serpent, having subsequently bitten himself, died in twelve minutes.

Sir Everard Hume has described at full length the case of a man, who was bitten on the thumb and fore-finger by a rattle-snake between four and five feet long in this country. He died eighteen days after the accident. Great swelling of the whole limb up to the axilla ensued; the tumefaction did not extend to the neck, but there was a fullness down the side, and blood was extravasated as low as the loins, producing a mottled appearance. A full trial was given to the volatile alkali, both externally and internally, and to other medicines of the like nature, as ether, brandy, &c. also to opium. The cellular substance had sloughed over the whole swelled part of the limb, so that the skin was separated universally from the muscles. For a further account of this case, and

REPTILES.

and of some other cases of bites of East and West Indian serpents, see the Phil. Trans. for 1810, p. 75.

Ruffel, in his account of Indian serpents, has furnished us with the most ample and interesting details concerning the Indian poisonous serpents. Of these the cobra de capello, or spectacle snake (coluber naja), and the katuka-rekula-poda (vipera elegans), are the most dangerous. It appears, from a comparison of the effects of the venom of the Indian serpents, the rattlesnakes, and the viper in the mammalia, that the symptoms are nearly the same in all, but that the term of their duration differs. The bite of a rattlesnake destroyed a dog in England in two minutes; while that of the most venomous Indian snake has never been fatal to this animal in less than thirty-seven minutes. A chicken bitten by the gedi paragooodoo (bungarus ceruleus) was immediately affected with stupor; in ten minutes, it was incapable of remaining upright; a quarter of an hour after it was stretched on the ground, as if asleep; it made some efforts to rise, turning the head to one side and the other, became convulsed, and perished in half an hour.

A stout dog was bitten in the thigh by a serpent of the same species: he howled much from the bite, but walked about freely. He lay down in a quarter of an hour, and howled: when an attempt was made to make him stand by raising him up, it was found that the hind limbs were paralyzed. He grew worse, ceased to howl, and vomited abundantly: he became benumbed, and remained lying on the side. He died in two hours, having had very bad convulsions.

A lean bitch, having been bitten near the groin, remained fifteen minutes without exhibiting any symptoms of suffering. In fifty minutes she lay down, and appeared much affected: on attempting to make her stand, it was discovered that the limbs were paralyzed. She vomited a little, and was convulsed till death, which occurred seventy minutes after the bite.

Wounds inflicted by the spectacle snake, or coluber naja, had the same effects; also those of the katuka rekula poda. Death did not always follow in the latter case, particularly in a dog, who was bitten six times, and once inoculated with the poison. A horse was bitten by the last-mentioned snake on each side of the nose. Prodigious swelling ensued, and extended to the throat; the animal refused his food, vomited, and appeared greatly affected. He had an emollient fomentation, and recovered on the third day.

Experiments with the bodroun had the same results: swelling, numbness, paralysis, convulsions, and death.

Ruffel tried inoculation of the venom with needles, thread, &c. Of six trials on dogs, none proved mortal. Eight out of twenty-four were fatal in chickens and pigeons.

Several venomous and innocent serpents were exposed to the spectacle snake: it would not bite them until instigated to do it, and they died without attempting to retaliate. But Ruffel found, in repeated trials, that two of these animals did not hurt each other; they would fight, and wound each other, but these wounds were not mortal.

Many circumstances modify the results of wounds inflicted by venomous serpents: viz. the quantity of venom, the condition of the serpent as to vigour or weakness, the number of bites he has inflicted, the situation and nature of the part bitten, the size of the animal, &c.

There are many facts to prove, that the secretion of the venomous gland, which is so active a poison, when introduced into a fresh wound, is quite innocent, and probably inoperative, if taken into the stomach. The psylli, or serpent charmers, so celebrated among the ancients for curing persons who had been bitten by vipers, sucked the wound

strongly and repeatedly. Recent wounds made by the fer de lance (vipera lanceolata) of Martinique, the venom of which is very active, are also sucked with impunity. Fontana swallowed the poison of the viper, both mixed with water, and pure; it had even a mild taste, instead of producing a caustic and burning sensation, as some have stated. The heads of vipers, with their fangs and glands entire, have been eaten by dogs without any ill effects; and even the head of the terrible rattlesnake, with all its venomous apparatus, has been employed, with the rest of the body, in making soup, which has been drunk with perfect impunity.

Having thus described the instruments with which nature has furnished the venomous serpents, for the purpose of attacking, killing, seizing, and swallowing their prey, we cannot be at much loss to understand how these objects are effected; yet the prevailing notions on the subject are calculated, instead of elucidating, to involve a plain matter in obscurity and mystery. These will be most effectually dispelled by the following statement of Palifot Beauvois, who had considerable opportunities of observing the habits of serpents in America. "Much has been written on the manner in which serpents seize their prey: some ascribe to them a kind of magical power, the effect of which is to charm and enchant the animals on whom they fix their looks; others, less fond of the marvellous, pretend that they inspire them with excessive alarm, that, not knowing what they do, they run from one side to the other, fly, return, and at last precipitate themselves into the jaws of the monster; a third opinion is, that serpents diffuse around a fetid odour, by the aid of which they suffocate birds, squirrels, rabbits, and the different animals on which they feed. It must be difficult to determine the means employed by these animals in a state of nature, for the purpose of seizing their prey; and it would probably be wrong if we were to suppose that the same means are adopted in all instances. Can we believe, for example, that the black serpent (coluber constrictor), which creeps with astonishing quickness, climbing shrubs, and not at all venomous, should employ the same means as the boiquira (crotalus durissus), a slow moving animal, never ascending the smallest plant, and furnished, like all the venomous serpents, with two fangs, the wound of which is so quickly fatal? Yet, if we may judge of these reptiles in a state of liberty, by what goes on when they are prisoners, they certainly create only a common alarm, such as any creature will feel, when endeavouring to escape from its enemy. The animals experience no enchantment, nor any attack of madness, when a serpent fixes his eyes on them. Serpents produce no bad smell, still less a fetid vapour, capable of suffocating animals. The boiquira eats indiscriminately all the dead birds brought to it. It will not eat frogs, which the black serpent, on the contrary, seems to prize highly. Fascination and charms are repugnant to reason: forcerers and magicians exist no more among animals than men: cunning, address, and force, are in both cases a sufficient, as well as the only charm and power, to render the weak tributary and victim to the strong.

"I made, in conjunction with Peale, the following observations on a boiquira, which he had preserved alive for five years, and on a black serpent.

"A living bird (icterus phenicus) was put into the cage with the rattlesnake, and remained there two days, without any offensive proceeding on the part of the serpent. The bird did not seem at all uneasy. As far as we could judge from the countenance, the air which it breathed was the same as it would be in an ordinary closed cage. During the two days, the reptile ate a dead bird of the same species

REPTILES.

as that in the cage, which he never offered to touch. Another living bird, the *loxia cardinalis*, instead of being frightened by finding himself in company with the boiquira, amused himself with pecking at the cage, and eating millet-seed thrown into him; he changed his situation frequently, and would even perch on the reptile's back; but he moved off at the sound of the rattle. Several kinds of frogs, living and dead, were presented to the same serpent; but he touched none. The black serpent, on the contrary (*coluber constrictor*), attacked the frogs immediately, and seemed to prefer the tree-frogs. He also swallowed flies and other insects.

"A common rat was put into the cage with the boiquira, who immediately appeared animated; the rat, frightened, ran towards the side opposite to the reptile. The chase lasted a few seconds, the animal using every effort to escape, when the reptile, perceiving a favourable moment, flew at his prey, and bit it. The rat continued to run round the cage, but the serpent remained quiet: the former, in about a minute, swelled, became convulsed, died, and was swallowed by his enemy. These convulsions were probably considered by old observers as the effect of the charming power of the serpent, or of extraordinary fear; but they are a regular symptom of the action of the poison.

"Perhaps these experiments do not determine exactly the means which serpents employ for seizing their prey, so likely to escape them by running or flying: but they seem sufficient to authorize us in rejecting all ideas of fascination, or charm, of extraordinary terror or suffocating vapour. On the latter point, I can state, that nine boiquiras were kept for three weeks in the same box; when it was opened, at the end of this time, no particular odour was observed." Daudin's *Hist. Nat. des Reptiles*, in the edition of Buffon, by Sonnini, v. 5. p. 55. et seq.

Those serpents which have not this quick and effectual means of destroying their prey by the poisonous apparatus, accomplish their object in another manner. They throw themselves on the animal which they attack, twine round his body and limbs, and exert, in this manner, a compressive force capable of breaking the bones. When he is thus disabled from resistance, they smear him over with a mucous saliva, and swallow him gradually in the way already described. The enormous serpents of Africa and America, thirty or forty feet long, are strong enough to attack and overcome the larger animals, and can then swallow them entire. See the account of the boa aboma by Stedman, in his voyage to Surinam and Guiana; and of the boa constrictor, in Adanson's *Voyage au Senegal*, p. 152. et seq.

Proportion of the venomous to the harmless Serpents.—The number of serpents possessing venomous fangs is more considerable than has been generally supposed. "Ne tels horrentibus," says Linnæus, "execrabili veneno nimium severent, decimam quamque tantum speciem armavit imperans, et versipelles eos voluit, ut dubii omnes metucrentur ab omnibus." Yet Dr. Ruffel found seven venomous species among forty-three, which he observed; and the proportion of the venomous to the non-venomous kinds, among the serpents described by Daudin, in his *History of Reptiles*, is as 80 to 233. There are not more than 14 or 16 genera of serpents indigenous in Europe, yet among these are five vipers. Of the species described by Daudin, 201 belonged to the ancient, and 112 to the new continent: the venomous kinds formed a fourth in the former, and a fifth in the latter.

Daudin gives the following lists of the poisonous and harmless kinds.

Genera with poisonous fangs.

1. Bungarus.
2. Acanthurus?
3. Crotalus.
4. Scytale.
5. Lachesis.
6. Cenchris.
7. Vipera.
8. Platurus.
9. Langaha.
10. Clothonia.
11. Hydrophis.

Genera without poisonous fangs.

1. Boa.
2. Python.
3. Corallus.
4. Hurriah.
5. Coluber.
6. Enhydus.
7. Erpeton.
8. Eryx.
9. Anguis.
10. Ophifaurus.
11. Pelamides.
12. Acrochordus.
13. Amphibæna.
14. Cæcilia.

See his *Hist. Nat. des Reptiles*, v. 5. p. 22.

The following is given by Humboldt as a comparative enumeration of the venomous species in the old world, and in America.

In the old continent.

	Species.
Bungari - -	2
Crotalus - -	0
Scytalæ - -	3
Lachesis - -	0
Cenchris - -	0

See the *Recueil d'Observations de Zoologie et d'Anatomie comparée*, v. 2. p. 5.

Horny Covering of the Jaws in the Chelonian Order.—This substance is similar in its nature to that which composes the hollow horns of animals (see HORN); and there is no essential difference between it and that of the bill in birds. (See BIRDS, in *Comparative Anatomy*.) As in birds, this horny covering is spread over the opposed surfaces of the two mandibles; but the organ so covered is much less susceptible of motion in the testudines, as the upper mandible is always fixed in them. In general it is sensibly fibrous in its texture, but sometimes it appears homogeneous. It is very hard, so as to enable these animals to break shells with facility. In this respect, it is analogous to the horny bills of the birds of prey, and the resemblance is so striking in one species of turtle, that it has received the name of hawk's-bill. It is formed on a vascular substance covering the bone, as is the case with the hollow horns and the bill of birds. The edges are sometimes simple, sometimes serrated, sometimes divided into large unequal teeth; the extremity is either entire and rounded, or grooved, or brought to a sharp point. The edge of the upper jaw is terminated by a thin sharp plate of horn, within which the lower passes to some height, being rather narrower in its transverse measurement: hence any substance may be cut by them as with scissars, for the outer margin of the lower jaw is also brought to a sharp edge. Besides this sharp edge, there is a covering of some breadth in the upper jaw, forming a ridge

REPTILES.

a ridge towards the anterior part, received into a corresponding concavity of the lower jaw.

Salivary Glands.—We have already observed, that nothing deserving the name of mastication takes place in any reptile. They live on other animals, and almost universally swallow them whole. Some testudines feed on shell-fish, and break the testaceous coverings with their horny mandibles, but they do not *chew* the contained animals. The salivary apparatus mult, therefore, be very different from that of the mammalia.

Several reptiles, however, require the assistance of fluids poured into the mouth for seizing and swallowing their prey. Some, as the frog and camelion, dart out the tongue, covered with a viscid matter, upon insects, which are entangled in the slime, and thus captured. Serpents spread a frothy slaver over the animals which they swallow, to facilitate their passage.

In some reptiles the tongue is composed, in great part, of a thick glandular mass, formed of numerous small tubes united at their bases, and separating towards the surface of the tongue. They are so many papillæ, giving a brittle appearance to the organ, or rendering it villous, when they are very small. The sides of the mass are perforated by numerous pores, through which the secreted fluid escapes. This gland rests on the muscles of the tongue, and follows the motions, which they communicate to the organ. The gland in question exists in the chelonians; in the testudo græca the structure just described is very evident. It exists also in several saurians, as the flat-headed gecko (*G. fimbriatus*), the common iguana, and the Schneiderian scink.

In the agame umbra (*iguana umbra*, Linn.) the gland is surmounted in front, instead of papillæ, with transverse plates closely arranged. These laminae cover the whole surface in the camelion.

The tongue seems to be covered by an analogous glandular substance in the batracians.

Where the tongue is scaly, or smooth, and covered with a simple membrane, the place of this gland is supplied by two others, elongated and glandular, situated under the skin, along the external surface of the branches of the lower jaw-bone, and pouring out their fluid at the outside of the teeth of the same jaw. In this direction they are in contact with the palatine membrane. These glands are strongly marked in the tupinambes, the colubres, and the boas. In the amphibænz the glands are not situated in the same place, although they have the same apparent structure. They lie immediately under the tongue, between the genio-glossi and genio-hyoidei.

The conglomerate gland secreting the poisonous fluid of the venomous serpents is spoken of in the description of the teeth.

The *os hyoides* varies in the different orders of reptiles, but it approximates in general very nearly to that of birds, from which it does not differ essentially in the saurian and ophidian orders. As in birds, its connections with the larynx are very inconsiderable: there is no muscle passing between them: a simple membrane is the medium of union. They are, in fact, completely separated in some genera of saurians; as, for example, the camelion: and the same observation may be extended to all the ophidians which have a tongue included in a sheath. This circumstance completes the proof of what is rendered very probable by many other reasons, that the essential function of the *os hyoides* is to support the tongue, and assist its motions.

The form of the *os hyoides* varies much in the chelonians: sometimes the body is nearly square, thin, and flattened, then the posterior cornua are straight, articulated to

the posterior angles of the body, separating from each other as they pass backwards, and having the larynx placed in their interval. The anterior cornua are consolidated to the body, a little behind the anterior angles, directed backwards, and curved upwards behind the occiput. In front the body is prolonged into a point, under the tongue, which it supports. Such an *os hyoides* is seen in the testudo græca. But in the matamata (*testudo fimbriata*, Gmel.) the body is very solid, bony, and pyramidal, with the basis turned forwards. The anterior cornua, forming angles towards the front, are articulated behind each angle terminating the basis; while the posterior, more slender, and bent like an arc, are fixed near each other to the apex of the pyramid.

Usually the *os hyoides* consists merely of cartilage in the saurians, as in most other reptiles; its parts are generally slender, elongated, and consolidated with each other. Yet it preserves in the crocodile that flattened shield-like figure, which we have described it to possess in the chelonian order, and which we shall discover also in the batracians. There are only two cornua, articulated nearly in the middle of the sides of the cartilaginous plate. They seem formed of two portions united together, but distinguished by a kind of angle projecting posteriorly.

In the common iguana (*I. delicatissima*, *lacerta iguana*, Linn.) the body may be considered merely as the point of union of the seven cornua composing the *os hyoides*. An anterior one is continued under the tongue, without being fixed to it. The six others are behind. The two lowest are the longest; they are contiguous, slightly curved, and enter the goitre, without affording attachment to any muscles or ligaments. The four others are true cornua of the hyoid cartilage. Two pass first forwards, but quickly bend backwards, and then upwards, to reach the occiput. The others are bent backwards and upwards, so as to remain nearly parallel to these. They are analogous, in their form and use, to the corresponding parts in birds. The cornua belonging to the goitre are found also in the scinks, agames, and dragons. In the dragon rayè (*draco lineatus*) their extremity is attached to the large bag forming the goitre, and will draw it inwards, when the tongue passes out of the mouth. These cornua are not found in the other saurians. Sometimes there are only two hyoideal cornua, as in the gecko *fimbriatus*. They are always perfectly analogous to those of birds.

The *os hyoides* of the camelion has four; of which two are straight and directed obliquely forwards. The two posterior go behind the head. The body is prolonged to nearly the anterior third of the tongue, when that organ is in the state of repose: it is cylindrical and slender in the whole of this part, which is between one and two inches long.

In the lizards and tupinambes, the number of cornua is also four. The anterior are formed of two pieces, consolidated, or moveable on each other, of which the first is directed forwards, while the second turns backwards, and is curved towards the occiput.

In the ophidians, with a tongue inclosed in a sheath, the hyoid cartilage is composed of two parallel threads, directed from before backwards, approximated to each other, separated in their anterior half by the sheath of the tongue, and in the rest of their extent by the two hyoglossi. The two threads are united in front, nearly between the posterior extremities of the branches of the jaw, being bent into a femicircle under the sheath of the tongue; from the convexity of their union a short point is continued under the sheath. In the other ophidians, as the amphibænz, &c. the

REPTILES.

the hyoideal cartilage has a triangular figure: the two posterior angles are elongated to form the cornua.

The os hyoides forms a broad nearly square plate, immediately applied to the inferior parietes of the palate and back of the mouth, in all the batracians, except the salamanders. The anterior cornua go off towards the front from the anterior angles, separate more widely before they turn backwards, then are continued towards the angle of the jaw, and curved from below upwards, in front of this angle, to be fixed to the posterior part of the cranium. The posterior horns are straight, strong, bony, not consolidated with the square plate, but articulated to its posterior angles, and directed obliquely backwards and outwards. The larynx is placed between them. The hyoid cartilage of the salamanders has a triangular form: the cornua go off from the posterior angles, and ascend at the sides of the neck. Their posterior edge is consolidated to a thread of the same nature, bent in the form of a handle, and having its anterior extremity united to that of the opposite thread in the middle of the posterior concavity of the hyoid cartilage. On each side of the branches of this cartilage, towards the front, there is a broad cartilaginous plate, nearly parallel to them, and only joined by muscles which go from one to the other. It seems to hold the place of an anterior horn.

In the thirty-fourth plate of the fifth volume of the *Leçons d'Anat. comparée*, there are figures of the os hyoides of the iguana, the Nilotic crocodile, the Nilotic tupinambis, the *laeerta agilis*, the gecko *fimbriatus*, *amphibæna*, another serpent, the *testudo græca*, the salamander and frog.

Muscles of the Os Hyoides.—In those saurians, which have a more or less protractile tongue, these muscles contribute greatly to its elongation, by carrying the bone forwards.

We find in reptiles; 1st, a muscle analogous to the mylohyoideus. It is composed, in the two first orders, of several portions; viz. an intermaxillary, fixed to the lower edge and internal surface of the branches of the lower jaw; a second very thick, ascending behind each angle of the jaw, upon the digastricus, and attached to the occiput; a third passing to different distances in the neck, fixed to the skin above, and embracing the neck like a girth. It is analogous to the cutaneous colli; and embraces the whole extent of the neck in the chelonians. In the common iguana the intermaxillary portion does not extend to the arch of the chin; and in the gecko there is only a thin aponeurosis reaching so far. But, in general, the mylo-hyoideus is fixed to the os hyoides in these two orders, which is not the case in the batracians; in which the muscle seems to exist merely for the purpose of filling the wide interval between the maxillary branches, and supporting and elevating the parts above it. Its fibres are directed transversely from one branch to the other; they are divided in several species by a median line, and attached to the internal surface of the maxillary branches, which enables them to elevate more advantageously the subjacent parts. In the *rana ocellata* the posterior edge is separated on each side, to ascend within the angle of the lower jaw as high as the palatine membrane.

2. The muscle analogous to the sterno-hyoideus is attached in the chelonians, between the two cornua of the same side, and to the posterior cornu; it descends along the neck, passes within the first bone of the shoulder, and is inserted on the inside of the neck of the second bone. It rests, in this course, against the sides of the œsophagus, and is strongly attached to the pharynx towards its anterior extremity.

The same muscle, in the saurians, is attached on the outside of the sternum, between the sterno-mastoidei, and is fixed to the posterior cornu of the hyoid cartilage. In the

iguana, it is fixed to nearly the whole posterior edge of the first part of these cornua; in the gecko *fimbriatus*, to the middle of this edge. In the caïman, after touching the os hyoides, it is continued to the lower jaw, and inserted far back in its lower edge.

It is much elongated in the cameleon, and carried far backwards on the outside of the sternum, forming a point in the same direction. This muscle covers another, thinner and broader, but of the same length, equally contiguous to its fellow of the opposite side in the two posterior thirds, and inserted in the extremity of the posterior cornua of the os hyoides. It might be named sterno-ceratoideus. In the *agame umbra* (iguana umbra, Linn.), the same muscle extends equally backwards on the outside of the sternum. The sterno-hyoideus has two portions in the crocodiles, which are only separated beyond the sternum: the lower one is thinnest, and inserted in the edge of the hyoid plate; the outer, broader and thicker, reaches the posterior edge of the cornu, and after a slight tendinous intersection, which serves to attach it to this cornu, is continued in the same direction to the jaw, and forms the first layer of the cerato-maxillary muscle.

In the serpents, the place of the sterno-hyoideus is supplied by a costo-maxillary muscle, extending from the anterior ribs to the lower jaw. Its internal fibres go from the jaw and the ribs to the hyoid cartilage.

It is prolonged, in the batracians, except the salamanders, within the sternum, to the farthest end of this bone, where it is fixed; or it only reaches the middle of the sternum. Many of its fibres are expanded on the pleura. In front it is divided into several portions, inserted successively in the external edge of the hyoid plate. One of these goes as far as the anterior cornua, and is fixed to it by a slender tendon. In the salamanders, the sterno-hyoideus is continuous with the rectus abdominis, and partakes in its motions.

3. The omo-hyoideus does not exist in the ophidians.

In the chelonians it ends in the sheath of the mylo-hyoideus, which incloses the extremities of the anterior cornua of the os hyoides. This muscle is very considerable in some saurians. In the gecko, for example, it is widened, to be inserted in the greatest part of the posterior cornua: it covers the greatest part of the sterno-hyoideus in front.

In the iguana it is contiguous to a muscle, which has the same direction: it is attached to the clavicle behind, and above the body of the hyoid cartilage in front. In the caïman it is also composed of two portions. The external, which is soon detached from the following, is fixed to the palatine membrane near the lower jaw. The internal is attached to the angle of the hyoideal cornu.

It is long and slender in the cameleon; it passes on the outside of the sterno-ceratoideus, and is fixed to the body of the os hyoides, on the outside of the sterno-hyoideus.

The omo-hyoideus of the frog is mentioned in the account of the muscles of the shoulder.

4. Muscle analogous to the stylo-hyoideus. This has only been noticed in the frogs and toads. It comes from the back of the head, behind the ear, where it is attached at the side of a muscle analogous to the sterno-mastoideus. It is divided into two portions in the *rana ocellata*, and into three in the common frog: they are all attached to the posterior cornu.

5. The genio-hyoideus. The chelonians have only one, the tendon of which is fixed to the arch of the chin: the two fleshy portions separate as they go backwards, and are fixed to the basis of the posterior hyoideal cornua. In several saurians the structure is nearly the same; as in the common iguana, and the caïman, for example. It consists of two portions

REPTILES.

portions in the cameleon; an internal long and slender one, inserted in the body of the os hyoides; an external broader and stronger, contiguous to the former, and attached to the posterior cornua in their whole length: it has an attachment also to the anterior cornua.

In the ophidians the genio-hyoidei are continuous behind with the costo-hyoidei. They are only observed in those whose tongue is not inclosed in a sheath.

The genio-hyoidei are divided behind into two portions, in the batracians. The external and shortest is inserted on the side of the hyoideal plate above its edge; the internal is prolonged on the posterior cornua, and furnishes a sheath to the hyoglossus. The sterno-hyoideus penetrates between these two portions, to be fixed to the plate.

6. The cerato-maxillary muscles. These are analogous in their attachments and use to the conical muscles of the os hyoides in birds: they only differ from them in not being turned round the cornua. They are found in the three first orders, but do not exist in the batracians. They arise from the posterior third of the internal surface of the branches of the lower jaw, and proceed backwards and inwards to the posterior cornua of the os hyoides. There are two on each side, attached to the four cornua, in the iguana. This animal has, moreover, a transverse muscle of the cornua, the fibres of which go obliquely outwards from the anterior to the posterior cornu of the same side.

In the agame umbra the last muscle is long and slender, continued from the extremity of the posterior cornu to the angle of the anterior.

In the chelonians, the cerato-maxillary are inserted into the extremities of the anterior cornua.

The tongue varies considerably in this class of animals: it is employed, in many instances, as the means of procuring their food, by those reptiles which feed on insects. But as none of this class masticate their aliment, or swallow it like the mammalia, the form of the organ is very different from that which it exhibits in the mammiferous animals.

The chelonians have a small pyramidal tongue, with the basis turned backwards, the apex forwards.

A large part of the saurians and ophidians have a tongue capable of considerable elongation. The most remarkable example occurs in the cameleon, where it is not larger than a quill, but five or six inches long: it is expanded at its extremity, which is covered with a viscous secretion. This weapon lies commonly in a sheath at the bottom of the mouth, contracted to the length of about an inch, or less. The animal can dart it out at pleasure, when the viscous fluid at its end entangles the prey, which is taken into the mouth with great celerity. "Quand les caméléons veulent manger," says Belon, "ils tirent leur langue, quasi d'un demipied, ronde comme la langue d'un oiseau nommé pic-vêrd, semblable a un verre de terre; et a l'extrémité d'icelle ont un gros nœud spongieux, tenant comme glu, duquel ils attachent les insectes, favoir est fauterelles, chenilles & mouches, et les attirent en la gueule. Ils poussent hors leur langue, la dardant de roideur aussi vitement qu'un arbalète ou un arc fait le trait." Pierre Belon, Observations, &c. liv. ii. ch. 34.

In the common lizards, the tupinambes, &c. the tongue is smooth, extensile, and terminated by two long flexible points, although semi-cartilaginous and nearly horny: it resembles perfectly that of the ophidians, excepting the anguis and amphibœna, and perhaps also the cœcilia, which have it flat, and merely forked at the end, without the power of elongating it.

In most of the serpents, the tongue, when contracted, is contained almost entirely in a membranous sheath. The

mechanism belonging to these projectile tongues partakes both of that which is found in some mammalia, as the echidna and the ant-eaters, and of that of birds. (See MAMMALIA and BIRDS, in *Comparative Anatomy*.) It depends on muscles acting on the os hyoides, and also on the muscles of the tongue.

The itellios and iguanas have a fleshy tongue, villous on its surface, and possessing about the same mobility as that of the mammalia. In the scinks and geckos it differs from the former only in being fissured at the end; and it resembles, in this respect, that of the angues, between which and the scinks there is in all points much analogy.

The tongue of the batracians is not only different from that of other reptiles, but also from that of other animals. It is fleshy, of a flattened figure, smooth, and covered, in all of the frog and toad kind, with a tenacious mucus. It is villous in the salamanders, and covered with very long papillæ in the horned frog (*bufo cornutus*, *rana cornuta*, Linn.). The great peculiarity of the tongue is its being attached by the basis to the front of the mouth, to the symphysis of the lower jaw. This is its thickest part: it is continued backwards in a thinner form, so as to end in two loose and flat portions, representing the apex, and lying in the back of the mouth. This loose part, ordinarily turned back towards the throat, is projected from the mouth, covered by its viscous secretion, upon the small insects which the animal feeds on, and which are thus entangled and swallowed.

Muscles of the Tongue.—They possess nothing peculiar in the chelonian reptiles, which have not an extensile tongue: they consist merely of two pairs. The hyoglossi come from the anterior half of the posterior cornua, and penetrate into the tongue at the sides of the basis.

The genio-glossi are very strong and broad in the vertical direction: they come from the front of the lower jaw, and enter the tongue more outwards and forwards than the preceding, with which their fibres are interwoven. The apex of the hyoid cartilage penetrates between them: they are also separated by a small cylindrical cartilage, to which each muscle is fixed; which is prolonged behind under the body of the hyoid cartilage, extending in front to the apex of the tongue.

The saurians have in general three pairs of muscles going to the tongue from the os hyoides or the arch of the chin, and a proper muscle attached to the organ only.

1. The hyoglossus comes from the cornua of the hyoid cartilage. In the common iguana it is attached to the posterior cornua, opposite the omohyoideus. In the gecko *fimbriatus* it is fixed to the middle of the cornua, at the side and within the cerato-maxillaris: it forms, with the straight genio-glossus, the basis of the tongue, and mixes its fibres with those of the proper muscle. The hyoglossus is long and cylindrical in the lizards and tupinambis: it comes from the extremity of the posterior cornua, approaches the opposite muscle as it advances forwards, becomes contiguous to it at the basis of the organ, towards the extremity of which it terminates in forming the two portions of cylinders, of which this tongue consists. In the cameleon it is fixed to the whole anterior edge of the posterior cornua, and is very thick at that part. Beyond the angle formed by the two cornua of the same side, it is curved and continued directly forwards. The fasciculi of fibres, of which it consists, are inserted in the posterior half of the sheath of the tongue, which it serves to draw backwards.

2. The straight genio-glossi come from the inferior edge of the arch of the chin, and are continued to the basis

REPTILES.

of the tongue; where they meet the hyoglossi, with which their fibres are interwoven.

3. The transverse genio-glossi are attached to the arch of the chin, and to the anterior part of the inferior maxillary branches, on the outside of the preceding. Instead of being narrow and elongated, they are broad and short. Their fibres pass obliquely from without, inwards and backwards upon the membrane of the mouth, as far as the sides of the tongue; which they will draw outwards and forwards. The two last pairs of muscles do not exist in the camoleon.

4. The proper muscle is found in those saurians only, whose tongue admits of elongation. It is composed, in general, of annular fibres. In the gecko fimbriatus, which has a broad tongue, this muscle is divided in front into six or eight small portions, which are united into two towards the middle third of the tongue, and then into one on each side, which form the two pieces of the basis of the tongue.

In the camoleon the annular muscle is very thick, and forms a fleshy cylinder surrounding the anterior three-fourths of that part of the os hyoides which penetrates into the tongue. Towards the front it is divided on the sides into two portions, a superior and an inferior; the latter is folded back towards the sheath of the tongue, to which it adheres. There is, moreover, a muscle proper to this sheath, which may be called the retractor muscle. It comes from below the glandular part, and is continued, on each side, as far as the part that is puckered up. When the hyoglossus throws this latter part into wrinkles, and shortens it, and the os hyoides is carried backwards by the sterno-hyoidei and ceratoidei, the retractor muscle causes the end of the sheath to remain applied to the extremity of the annular muscle which recedes, because then its posterior attachments are the most fixed: on the contrary, when the extremity of the os hyoides and the annular muscle push the sheath forwards, the anterior attachments have a point d'appui; the posterior portions of the retractor draw forwards the sheath, and unfold it.

By putting together what we have said concerning the os hyoides and its muscles in the camoleon, in a former part of this article, and what we have just said of the muscles of its tongue, it will be easy to understand how this organ can be elongated, and withdrawn into the mouth. The first office is performed by the annular muscle, with the cerato-maxillary, and the genio-hyoidei. The sterno-ceratoidei and hyoidei carry backwards the os hyoides, at the same time that the hyoglossus shortens the sheath and puckers it up.

In most of the ophidians the tongue is inclosed in a membranous sheath, which opens behind the interval of the branches of the lower jaw, and is continued backwards between those of the hyoid cartilage, under the trachea. It is lined internally by the membrane of the mouth. This sheath is carried forwards by a pair of muscles analogous to the genio-glossi. They derive their origin by two portions, one of which comes from between the two branches of the lower jaw, the other from their extremity; they come together and are fixed to the sides of the sheath to its most distant extremity. The hyoglossi are two elongated muscles, contiguous, and even united together by fine cellular laminae. They exactly fill the interval of the cornua of the hyoid cartilage, and are even doubled backwards round their extremity. These muscles go to the basis of the sheath, and draw it backwards, when it has been carried forwards by the two first pairs.

The proper muscle is formed of two cylinders, first lying

together, and separated towards the anterior third of the tongue, for the two portions of which its apex consists; here they become considerably diminished, and are reduced to a mere thread at the end.

This simple apparatus, combined with that of the os hyoides and its muscles, gives to the tongue of the serpent that wonderfully quick power of extension and retraction. Carried forwards by the genio-vaginal muscles, brandished by its proper muscles, it re-enters the sheath in consequence of the elasticity of the hyoideal cornua, which tend to restore themselves, and of the action of the hyoglossi. One or other of these actions is assisted by the costo-maxillary muscles, according as the portion analogous to the sterno-hyoideus, or that which corresponds to the cerato-maxillary, contracts. The extension of the tongue out of the mouth is so much the greater, because it is effected through an orifice near the extremity of the snout, and because its basis may be brought near to this part.

In the amphibianæ, which have a flattened tongue, not inclosed in a sheath, nor susceptible of extensive motion, there are, 1st, two genio-glossi attached to the arch of the lower jaw, more internally than the genio-hyoidei; 2dly, two hyoglossi; and 3dly, two cerato-glossi, which present nothing worthy of particular notice.

The tongue of the batracians, as we have already described, is fixed in front to the arch of the lower jaw, and free behind. In passing out of the mouth, and going back again, it turns upon the fixed point of its attachment to the jaw. Two pairs of muscles, the genio-glossi, and the hyoglossi, execute these motions. 1. The hyoglossi form, in the rana ocellata, two cylindrical masses, lying on, and attached to, the posterior cornua. They soon unite into a single mass, which rests on the hyoideal plate, and penetrates the tongue in front of this plate, expanding into small fasciculi, which reach to the loose edge of the organ. 2. The genio-glossi form at first two small spherical masses, placed at the arch of the chin on the small transverse muscle; they are subsequently elongated into two contiguous cylinders, of which the fibrous fasciculi separate from each other, decussate with those of the preceding muscle, and go to the loose edge of the tongue. While the tongue is in the mouth, the hyoglossus is folded on itself, and the genio-glossus is straight. The latter muscle is folded, and the former straight, when the tongue has been projected. In the common frog, these two pairs of muscles are not so minutely divided in the tongue, and the genio-glossi do not form spherical masses towards the arch of the chin: in other respects they are similar.

Tongue of the Crocodile.—Humboldt has observed a peculiar mechanism in the tongue of this animal, bearing an evident relation to its wants and habits, of which the following is a description in his own words.

“From the most ancient times disputes have existed concerning the tongue of the crocodile; some naturalists pretended that it was entirely wanting, others affirmed that it was very short, and placed at the entrance of the œsophagus. According as one or the other of these opinions prevailed, the sculptors and antiquaries of Rome amused themselves with destroying or restoring the tongues of their crocodiles. When we examine attentively the os hyoides of this animal, we find that it is in consequence of its form and small size that a part or rather a fold of the tongue has been confounded with the whole organ. There is in this animal a peculiar mechanism, by which a valve is formed, interrupting the communication between the mouth and throat. When the crocodile appears motionless on the bank of the river, with the jaws opened at an angle of

REPTILES.

95², the whole mouth appears yellow: the valve is elevated, and the opening of the fauces is not seen. If we surprise him, the valve is generally depressed; and if a person runs the risk of approaching sufficiently, a round body of a beautiful red colour, which is the opening of the glottis, may be perceived. This valve enables the crocodile to seize his prey under water without running the risk of being inundated by the great quantity of fluid that would pass into the œsophagus. When he swallows, the valve must be depressed, and the animal on dry ground. The os hyoides of the crocodile of the Orinoco is a membranous spatula, broad, concave, and terminated by two short horns. The os hyoides of the Egyptian crocodile, as delineated by Mr. Duverney, is altogether different from that of the South American animal; another proof of the distinction between the crocodiles of the old and new continent. In an animal of eighteen feet, the tongue is twenty-five inches: it is yellow, fleshy, and covers the whole jaw; but it is attached on all sides, so that the os hyoides cannot elevate it to the end. The anterior or spatula-shaped portion of this bone enters the membranous substance of the tongue, which it can elevate at a right angle. As the sides and extremity of the organ are fixed, this motion of the bone can only carry with it the membranous part of the tongue, which forms the fold presenting itself like an elevated valve. The os hyoides is depressed, and the valve immediately disappears. Three conditions are necessary to the execution of this mechanism, a tongue attached to the lower jaw; a ductile and flexible membrane covering it; and an os hyoides broad in front. The yellow substance in the anterior part of the mouth belongs to the tongue as well as the fold covering the entrance of the œsophagus. Humboldt found that the tongue swelled very much, when subjected to Galvanic influence, by means of zinc and silver. See *Recueil d'Observations d'Anatomie comparée et Zoologie, faites dans le Voyage de Humboldt et Bonpland, t. 1. pag. 9. pl. 4.*

Geoffroy gives a similar description of the tongue, os hyoides, and their mechanism, in the Nilotic crocodile. He describes it as a yellowish, shagreened skin, exactly like the substance of the palate, pierced by numerous small holes, the excretory ducts of the glands situated on its upper surface, and adhering on all sides to the branches of the lower jaw. He speaks of the broad anterior part of the os hyoides forming, by its elevation, a veil, which covers all the back of the mouth. Thus, the animal can remain under water with the jaws open, and receive air through the nostrils, the only part above the surface, without the water entering the throat or trachea. *Annales du Muséum, vol. ii. p. 42, et seq.*

Epiglottis.—In most reptiles the opening of the glottis is neither covered by a valve, as in the mammalia, nor armed with papillæ, as in birds. Yet a kind of epiglottis may be observed in the common iguana, and in the Schneiderian scink. There is a rudiment in the crocodiles; it does not appear in several other animals of the same order, nor in the chelonian, ophidian, and batracian reptiles. The cylindrical larynx of the dragon, and its simple opening behind the root of the tongue, are very well represented in Blumenbach's *Abbildungen Natur-Historischer Gegenstände, N^o 98.* Is the absence of the epiglottis connected with the peculiar modification which respiration undergoes in this class? or with their deglutition? On the former point we may observe, that, as they breathe only at considerable intervals, there is no danger of the glottis being opened during swallowing, and its edges may consequently be kept closely approximated. Again, as they swallow their food whole, it is not likely to pass into the larynx.

Fauces.—The openings of the nostrils are situated very forwards in reptiles, and are not closed by any moveable curtain, as in the mammalia. A kind of immoveable valve, attached to the anterior edge of the opening, and leaving the orifice free behind, may be seen in the gecko sim-briatus.

There is something analogous to the *velum palati* in the crocodile. The nostrils open far back, contrary to what we have mentioned concerning other reptiles. They form a round aperture in the most distant part of the arch of the palate. The membrane lining this concavity forms a loose production a little in front of the opening in question, which descends on the sides, growing a little broader, until it meets another elevation behind the basis of the tongue. These form together, by their loose edge, the *isthmus faucium*, or entrance of the throat. The first affords some protection to the opening of the nostrils, but cannot entirely close it; the latter contributes, with the rudiment of the epiglottis already mentioned, to cover the glottis.

The entrance of the throat is large in all reptiles, and capable, in many, of still greater size, by the expansion of the lower jaws. There is nothing deserving the name of *isthmus*. They swallow entire animals, which cannot pass into the nostrils, and hence do not require a *velum palati*.

Pharynx.—As the nostrils open forwards in reptiles, the pharynx has not the same relation to the nasal cavity, as in the mammalia and birds. The mouth and larynx communicate with it, and there is usually a large aperture corresponding to the Eustachian tube.

The pharynx can hardly be distinguished from the commencement of the œsophagus in reptiles. Their diameter is usually the same; and there is absolutely no difference in the aspect of the membrane forming their internal parietes. It presents a great number of longitudinal folds, which are effaced when a prey of large size is swallowed. There is no exterior muscle enveloping the entrance of the canal.

Deglutition may be assisted, in the chelonians, by the action of the *sterno-thyroides*, which rest on the œsophagus in the whole length of the neck; and even adhere in front to its parietes, and to the part which may be regarded as belonging to the pharynx. The os hyoides may also contribute to deglutition, by means of the muscles which elevate it.

This office is particularly evident in the batracians, and especially in the frogs and toads. The hyoideal plate, which supports in these animals the extensive parietes of the back of the mouth and palate, is put in motion by the *mylo-hyoideus* and the muscles analogous to the *stylo-hyoidei*, only for the purpose of elevating these parietes, and applying them to the concavity of the palate. There is also another muscle coming from the upper and back part of the head, in front of that which corresponds to the *stylo-hyoideus*; it is narrow at its origin, but expands as it passes forwards and downwards, and as it covers that part of the throat which is prominent behind. It is continued to the edge of the hyoideal plate, in which it is inserted, its fibres adhering also to the membrane of the throat, on which they lie. Their action will elevate the hyoideal plate, and apply the membrane which they cover to the opposite surface of the cavity.

The longitudinal fibres, belonging both to the pharynx and œsophagus, are more or less strongly marked.

Œsophagus and Stomach.—The former tube does not present those dilatations which we notice in birds: it retains nearly a uniform diameter throughout, or the change, if any, is gradual. But this diameter is, in most cases, much more considerable, in comparison with that of the stomach, than in the two preceding classes. Under certain circumstances, indeed, the œsophagus is larger than the stomach

REPTILES.

in the ophidians; for example, when the latter is not distended with food, because its parietes contract sooner after enlargement than those of the œsophagus. The membranes are the same in both, and, when the tube increases in size insensibly to the stomach, it is often very difficult to assign the limits of the two parts, and consequently the situation of the cardia. The stomach is generally without any cul-de-sac, oval and elongated: its parietes usually thin. The muscular coat is then hardly perceptible, at least in some part of its extent, and the cellular is confounded with the mucous or internal. The pylorus is usually without any valve; it is marked by a simple contraction, by the greater thickness of the parietes of the stomach, and by the different structure of the intestinal membranes.

In the turtle, the internal surface of the œsophagus is beset with long, hard, conical papillæ, of which the points are directed backwards, with the effect, apparently, of preventing the return towards the mouth of the matters swallowed by the animal. Such, at least, is the notion generally entertained of the end or purpose of this structure. But the absence of such provision in all other animals, where the necessity seems equally to exist, cannot but render us sceptical on the subject, more particularly as we know no facts concerning the nature of the food, the mode of its deglutition, nor any peculiar modification of surrounding or connected organs, to which this singular structure might be supposed to bear some relation. The stomach is gradually diminished in size from the cardia to the pylorus: it is bent on itself, and the portion beyond the curvature is thicker than the rest, in consequence of the muscular fibres being more copious. The internal coat has longitudinal folds in this part, but hardly any in the other. The situation of the cardia is well marked, and the œsophagus is distinguished from the stomach by the sudden dilatation of the latter. The pylorus has no valve.

Among the saurians, the crocodile has a peculiarly shaped stomach; it is very distinct from the œsophagus by its globular figure. Near the insertion of this canal there is separated from it below a small cul-de-sac, opening into the intestine by a very small orifice, and having its cavity separated from the great sac of the stomach by a kind of strait. Consequently the general cavity of the stomach is a large cul-de-sac, of which the parietes are very thick. The internal membrane forms considerable plaits arranged in a serpentine form, like the convolutions of the brain. The cellular coat, which is not very distinct from the mucous in the œsophagus, becomes more so in the stomach. The muscular nearly equals the two others in thickness; the coats are altogether much thinner in the small cul-de-sac.

In the other saurians there is no cul-de-sac. The stomach is oval and very elongated in the iguana, without curvature; the œsophagus dilates gradually to form it. The only mark that can guide us in determining the situation of the cardia is, the cessation of the longitudinal folds of the internal œsophageal membrane. The stomach is suddenly contracted, and bent a little before its termination at the pylorus. Its parietes become thick and opaque at some lines from this aperture, from an increase of the muscular fibres, of which the transverse are strongly marked. The internal coat forms no fold; there is no valve at the pylorus, which is very small.

In the tupinambis monitor the stomach forms a long tube, bent into almost a complete circle.

In the Schneiderian scink we again meet with the same elongated form, transparent parietes, and difficulty of distinguishing the stomach from the œsophagus, except by the longitudinal fold; of its inner membrane, and the thickness

of its muscular coat. But the posterior part of the stomach contracts suddenly, is bent towards the right, and a little elongated in this direction before it terminates. The parietes of the latter portion are more thick and opaque, and its internal membrane is folded longitudinally.

The stomach begins by a small dilatation in the cameleon, then it assumes a cylindrical and elongated form, and is bent on itself; it is considerably contracted before it terminates, and forms a small cylindrical canal, of which the internal membrane is folded longitudinally. The muscular coat is thicker in this contracted part than elsewhere. It forms a prominent ring at the pylorus.

In the dragon the stomach is shaped like a pear, of which the large end corresponds to the cardia; it has no curvature; its parietes are transparent; they become thicker and opaque near the pylorus; and these characters are the only circumstance, by which we can distinguish it from the beginning of the intestinal canal, which has thin and transparent coats.

The stomach is also pear-shaped in the gecko; the œsophagus makes a curve before it ends, and is inserted at one side of the basis. It is narrow, with thick coats, a strong muscular covering, and broad longitudinal folds of the internal or mucous coat. The sides of the organ are thicker at its extremities; and the pyloric end is a little bent. The internal membrane is smooth.

In the ophidian order the stomach is shaped like an intestine, hardly larger than the œsophagus, and without curvature. The internal membrane is folded longitudinally. When the stomach is empty, these folds are thicker than those of the œsophagus, which are not always observed.

The œsophagus of a snake, examined by Spallanzani, formed a cylindrical tube like an intestine, for about nine inches: it then became gradually narrower, so as to constitute a funnel of the length of four inches and a half. This funnel was the true stomach. The sides of the stomach were thicker than those of the œsophagus: no glands or follicles could be seen in the latter; but the stomach was abundantly supplied with them throughout its whole length; they discharge part of their liquor on being pressed, and the internal coat is moistened with it. Dissertations relative to the Natural History of Animals and Vegetables, v. i. p. 112 and 113.

In frogs and toads the stomach is shaped nearly as in the chelonian reptiles. At first considerably dilated in comparison with the œsophagus, it is gradually contracted, then curved so as to form an intestine-like canal, with thick coats, ending at the pylorus.

It is slightly curved only near its posterior extremity in the salamanders. Its figure is elongated and not much swollen; the parietes thick; and the internal membrane exhibits small rugæ. There is a fold near the pylorus, in the situation of the curvature. Figures of the stomach and intestines of various reptiles are given in Cuvier's *Leçons*, pl. 41.

Intestinal Canal.—Its length, in proportion to that of the body, is greatest in the mammalia, and diminishes successively in birds, reptiles, and fishes. In reptiles it is often hardly twice the length of the body, taken from the extremity of the snout to the anus. But tadpoles exhibit in this respect a remarkable peculiarity. Their intestinal canal is nearly ten times as long as the space between the snout and anus, while in the frog it is not more than twice the length of the corresponding space. Other important differences, which will be noticed subsequently, exist in the two cases. This shortness of the alimentary canal corresponds to the nature of the food in reptiles, which is derived from the animal kingdom.

REPTILES.

The following table of the length of the intestinal canal in various reptiles, is taken from the third volume of Cuvier's *Leçons d'Anatomie comparée*, p. 457.

Names.	Length of the body.	Length of the small intestine.	Length of the large intestine.	Length of the whole canal.	Proportion to the length of the body.
Testudo græca - - -	0.210	0.680	0.014	0.694	:: 1 : 3.3
Nilotic crocodile (adult) - -	1.690	5.384	0.406	5.790	:: 1 : 3.4
Nilotic crocodile (young) - -	0.240	0.710	0.036	0.986	:: 1 : 4.1

Salamander - - -	0.040	0.080	0.022	0.102	:: 1 : 2.5

* In a common snake of four feet in length, Blumenbach found the intestinal canal about three feet, nearly straight, or at least very slightly undulated: its proportional length was therefore different from that expressed in the table. *Specimen Physiol. Comp.* p. 30.

The intestinal canal of reptiles has in general no appendix to mark its division into large and small intestines; this division exists nevertheless in most of them. All the chelonians, most of the saurians, the ophidians, and the batracians, with the exception of the firen lacertina, have a long and slender intestine, inserted into a large and short intestine, and commonly prolonged into the cavity, so as to form a circular margin of a valve-like form. The sides of the large intestine are almost always thicker and stronger than those of the small. The membranes differ too; the muscular in respect to its longitudinal fibres, and the internal in its folds. The iguana is the only animal of this class, in which a true cæcum has been noticed.

Of the Intestinal Canal.—All reptiles have the intestinal canal very short, but not of the same diameter in its whole length. In the first and most considerable portion, the capacity is much inferior to that which it is found to possess near its termination; so that it may be divided, as in the mammalia, into small and large intestines. A circular valve is most frequently found separating the two divisions; it is formed by a prolongation of the small intestine, which becomes dilated, and sometimes is extended into a kind of sac, projecting more or less into the cavity of the large intestine, and rendering the parietes double at that part. It is thus found in the Schneiderian scink.

In tortoises, the diameter of the small intestine gradually diminishes from the pylorus to the point of its insertion into the large: the area of which is four times greater than that of the small, and its parietes have the same structure as in the other reptiles. The cavity is regular throughout, there being no partial dilatations or fæculi. The internal membrane has folds, more or less broad, and of a membranous structure, in different species, sometimes connected in a reticular form at the commencement of the small intestine, having a longitudinal and parallel direction in the rest of its extent, and arranged more or less irregularly in the large. The large intestine proceeds in a straight direction to the anus, whilst the small makes many irregular turns in its course.

Blumenbach found the intestinal canal of the hawk's-bill turtle (*testudo caretta*) five times as long as the whole animal. The small intestine, as it is called, was larger than the short portion of the large intestine; the whole internal surface was covered internally with an abundance of mucus. *Syst. of Compar. Anat.* p. 173.

The internal coat of the intestine of the turtle is covered with innumerable thin longitudinal processes, lying close together, and increasing the surface of the gut to a vast extent. They are most numerous in the upper part of the canal, and gradually diminish in number, until they cease altogether, below. In the latter respect they resemble the valvulæ conniventes of man, and the villi of all animals. For these structures are always most distinct at the commencement of the canal, where absorption goes on to the greatest extent. The alimentary matter is deprived more and more of its nutritious parts, as it descends in the intestine; and hence a less extensive absorbing surface is sufficient, in the lower part of the canal, for taking up the remains of really nutritious particles. Yet Blumenbach says that he found these folds so numerous in the rectum of the hawk's-bill turtle, that a section of the gut resembled a broad radiated band. *Lib. cit.* p. 173, note.

In the crocodile of the Nile, the small intestine may be distinguished into two portions, the one more capacious, having thinner coats, and making four turns in such a manner as to form four permanent angles; the other, more contracted and having thicker parietes, incloses between its internal and muscular coats a layer of glandular substance, semi-transparent, of a grey colour and pulpy consistence. In the internal membrane lining the glandular substance, there are seen longitudinal folds arranged in a zigzag form, and connected together laterally, by smaller folds, so as to form a reticular surface. In the first portion of the small intestine, where the glandular substance is not manifest, the folds arranged in a zigzag form are replaced by fine villous eminences. Near the termination of the small intestine there are only seen some waving folds, connected by a few, proceeding transversely. In the large intestine, the folds are arranged irregularly, forming a velvet-like surface.

The form of the rectum (under which term is included the large intestine of fishes and reptiles) is cylindrical in the crocodile of the Nile; and the small intestine, where inserted into it, is nearly of equal diameter. In the gavial (*Gangetic*

REPTILES.

(Gangetic crocodile), the large intestine has a pyriform figure, the termination of the small being inserted into its broadest part.

In the lizards, the rectum is cylindrical, and much broader than the small intestine which is inserted into it; the latter, after having turned forwards from the pylorus, is folded backwards, and proceeds in a tortuous direction as far as the rectum, which pursues a straight course to the anus. The parietes of the intestinal canal are thin and transparent; the internal membrane has folds arranged in a zigzag form.

In the cameleon, the coats of the intestine have the same structure; the capacity of the small is not much inferior to that of the stomach and large intestine, in the greatest part of its extent; but it becomes much contracted a little before its insertion into the latter. There is no valve indicating the separation between the different portions; the internal membrane has waving folds, the loose edges of which have a fringed appearance; they are directed longitudinally, and contracting as they approach the rectum, disappear at some distance from that intestine, where the internal membrane becomes smooth and without any folds. The muscular coat is thicker in the rectum than in the small intestine, where it is indistinct. The cellular coat is not manifest.

In the dragon, the intestinal canal forms two turns and a half before it arrives at the anus; the commencement is distinguished only by the different appearance of its coats, which are much thinner than those of the stomach.

In the iguana, the parietes of the intestinal canal are thin and transparent, gradually contracting from the pylorus to the insertion of the small intestine into the rectum; the latter is of an elongated form, but contracted at one part, by which it becomes divided into two portions almost of a cylindrical shape. The internal membrane has some folds directed longitudinally in the small intestine. In the common iguana, which has the intestinal canal long and very capacious, there is a true cæcum, distinguishable from the large intestine by the greater thickness of its coats, and by a partition separating their cavities, so that it is through a very narrow orifice that the fecal matter passes from the cæcum into the succeeding part of the large intestine. The insertion of the small into the former takes place near its middle. The coats of the cæcum have in some degree a facculated form. The internal surface is smooth and without folds. In the large intestine the internal membrane has the same structure, except at the commencement, where there are found about six transverse valves, which do not extend around the whole tube of the intestine. In the small intestine there are longitudinal folds. The pouch formed by the cæcum is about three-fourths of an inch in length, and twice as much in breadth.

In the gecko à gouttelettes the parietes of the intestine are also transparent, the small has but little capacity, but is unequal at different parts; it is inserted into the centre of the first portion of the large intestine, which is of a globular form; and is separated, by a contraction in its coats, from the second portion, which is elongated and oval, the small extremity corresponding to the anus. In the Schneiderian feink the thin and tender coats of the intestinal canal are much dilated at the commencement of the small intestine, and contracted at the part where it is introduced into the large. We have already mentioned that it is dilated into the form of a bladder, and enveloped by the first portion of the large intestine, similarly dilated. The excrements, which pass through the small aperture in the vesicular dilatation of the small intestine, find their way partly into the interval between the latter and the internal surface of the large. Beyond the first portion the rectum becomes cylindrical. The

small intestine is divided into many pouches by contractions which pretty nearly correspond to its different turns.

In the ophidian order the intestinal canal pursues a serpentine direction as far as the rectum, and preserves nearly the same diameter throughout, dilating but little in the large intestine. In the small, the internal membrane forms broad longitudinal layers, folded in the manner of ruffles; it is rugous, and in the rectum forms thick, irregular folds, which are continued to the anus. In the coluber natrix, according to Blumenbach, the whole length of the intestinal canal does not equal that of the animal. The small intestine forms a very considerable valve at its entrance into the large. Lib. cit. p. 174.

In the salamanders, the small intestine is very narrow in comparison with the rectum, where the internal membrane forms thick and fringed folds. In toads and frogs, we find a nearly analogous conformation and structure, there being only a slight variation in the form of the rectum, which is more or less of a conical or pyriform shape, as in many frogs, or cylindrical, as in toads. But in the tadpoles of both, the intestinal canal is altogether very different from that of the same animal in the perfect state. Long, narrow, and nearly of uniform diameter in the small intestine, making irregular turns in its course, its volume augments at the rectum, which becomes of a facculated form, and makes two spiral turns upon itself, before it proceeds to the anus. There is no valve separating the two portions of the intestine.

In the firen lacertina the intestinal canal proceeds almost in a straight course from the pylorus to the anus, making but one small turn near its middle, from which it proceeds straight to its termination. Its coats are transparent, and its diameter nearly equal throughout, not admitting of any division into small and large intestines.

Physiology of the digestive Organs.—Blumenbach asserts that most reptiles are omnivorous, while some are confined to one species of food, as the bufo or rana calamita, which feeds on a few species only of insects, and those alive. (Specimen Physiol. Comp. p. 29.) We cannot help doubting the accuracy of the first part of this statement; the food seems to us almost entirely animal. Serpents, frogs, and lizards, live on the smaller animals or insects; and even the turtles, which eat particular kinds of marine plants, feed also on the mollusca. The simple stomachs, the simple and short alimentary canals of the whole order, correspond very clearly to what we understand concerning their carnivorous habits. Newts seem to care for living insects and worms only, which they seize with their jaws, and swallow whole.

Two apparently contradictory circumstances have been noticed in this order; great voracity in many instances, but in all a wonderful power of abstinence. Salamanders sometimes devour their own excrement, and earth. Serpents often take in a quantity of food, which distends their bodies inordinately, and leaves them inactive, and hardly capable of motion. The salamanders will sometimes stuff themselves to such a degree with worms, that they crawl up again out of their stomachs. See Spallanzani's Dissertations, vol. i. p. 110.

"A newt," says Bonnet, "having devoured a large earth-worm, I supplied it with another above four inches long, and thick in proportion. It immediately swallowed the whole, except a line or two that hung out of the mouth; but the worm was soon thrown up, and the same repeated twice, but the worm still lived." Spallanzani's Tracts, vol. ii. p. 366.

The instances which are recorded of the abstinence of reptiles seem at first almost incredible. Not to mention the toads,

REPTILES.

toads which have been found inclosed in blocks of stone, and which probably have been in a torpid state, nor the more common instances (see L. Th. Gronovius ad Plinium de Aquatiliu Natura, p. 38.) we have the respectable authority of Caldesi for the fact of tortoises having remained without food, and not in a torpid state, for a year and a half. Blumenbach reports of a tortoise, which he kept for three quarters of a year, that the harmless creature never ate any thing the whole time, although every thing that the house and garden afforded was offered to him. For the last three months (from November to February) he exhibited the lowest degree of vitality, manifested, in addition to extremely slow locomotion, with almost closed eye-lids, merely by the single sense of touch or feeling, particularly of warmth and drafts of air. When he died, the muscles were as fleshy and fresh-coloured as in the best nourished tortoises. *Abbildungen, &c.* No. 66.

Redi had a land tortoise live eighteen months, a camelion eight, and vipers ten, without food. (*Spallanzani's Tracts, Introduction, p. 42.*) Toads were quite lively at the end of fourteen and eighteen months, inclosed in pots. *Ibid.*

Blafius mentions, in his "Anatomia Animalium," that a land tortoise which he kept ten months would take no food during the whole time.

Bonnet, speaking of newts, says, "these animals can support the want of food very long. Some of mine have lived two months without it. Sign. Spallanzani had remarked the same; and observed, that although long deprived of nutriment, they reproduced their members equally well as those plentifully supplied with sustenance." (*Spallanzani's Tracts, v. 2. p. 364.*) Blumenbach has kept salamanders eight months without taking food, or appearing to suffer from the want of it. (*Handbuch der Naturgeschichte, p. 220.*) Daudin asserts that snakes and vipers may be kept for six months without food, yet seem to lose none of their activity: t. 1. *Introd. p. 270.*

Some protei, which Dr. Schreibern of Vienna had kept in his possession for two years, had taken no food, and were quite well. (*Cuvier, Rech. sur quelques Rept. douteux; l'Anat. du Proté.*) Bruce stated that he had kept the cerastes in a bottle for two years without food, and Lacépède reports, on the authority of Shaw, that a Venetian apothecary kept two of these fasting for five years. (See Daudin, vol. vi. p. 186.) This power of fasting belongs, in a greater or less degree, to the whole order. For a comparison between the power of abstinence of warm-blooded animals and reptiles (the state of torpidity being excepted), see *Diss. Academ. Instit. Bonon. ap. Benedictum 14. Pont. Max. de fervor. Dei Beatificatione, lib. 4. p. 1. pag. 328.*; also *Beccarius in Comm. Instit. Bonon. t. 2. p. 1. pag. 223.*

No reptiles masticate: the herbivorous amphibia gnaw off the vegetable productions on which they feed, but they do not chew them. The structure of their jaws, teeth, and tongue, gives them the power of swallowing entire animals: this process of deglutition, being often exercised on animals as broad as themselves, and broader, is very slow, and occupies even hours. The œsophagus must of course possess a great power of dilatation. In his account of the newt, Bonnet says, "that worms are seized with a sudden motion of the animal's jaws, and swallowed alive, with gentle shocks of the whole body, and particularly of the anterior part. The prey is always swallowed without mastication: the minute teeth, which are not employed in chewing, serve to prevent the escape of the animal, which twists itself about most actively. Long worms are devoured entire, notwith-

standing all their exertions to escape. They twine round the neck of the newt like a serpent: every moment they become shorter, and gradually disappear. Thus have I seen a newt swallow a worm more than six inches long in less than five minutes. A large worm, seized by the middle, is seldom swallowed in the same position, because it is too large, if doubled in the mouth, and the newt gradually shakes it out, until it can seize one of the extremities; which being accomplished, the worm is soon devoured. However, I have observed a large one swallow a worm taken by the middle, without seizing an extremity; but a quarter of an hour was occupied in the meal. The successive motions of deglutition are very sensible; it is performed by repeated shocks. Though they have flexible jointed fingers, they make no use of the hand, either to seize their prey, convey it to the mouth, or retain it there." *Spallanzani's Tracts, v. 2. p. 364.*

The length and capacity of this tube, and its large communication with the stomach, are well suited to the nature of serpents. The prey, always swallowed without mastication, is often too long to pass entirely into the stomach: it remains in the œsophagus until room is made for it. Travellers have even asserted that one end of an animal sometimes hangs out of a serpent's mouth, while the other is in the stomach.

As there is no mastication in this class, nor any provision like the gizzard of birds, for comminuting the food when swallowed, the process of digestion must be effected by the action of the stomach alone on the prey swallowed entire. The juices of the organ are fully adequate to this effect; and the process has been demonstrated by experiment in several genera by Spallanzani. He inclosed food in tubes, and conveyed them into the stomach of the frog, the newt, and different serpents; and always found that it was dissolved in a longer or shorter time: it thus appears that the essential nature of digestion is the same as in the warm-blooded animals: but the process exhibits some modifications, as the different nature and habits of the animals would naturally lead us to expect. The chief difference is that the solution requires a considerably longer time than in warm-blooded animals. The flesh in the tubes, conveyed into the stomachs of frogs, was not completely dissolved until the third and even the fifth day. (*Dissertations, v. 1. p. 102.*) Yet although the gastric liquor of frogs acts so slowly, it is capable in time of dissolving even bone: Spallanzani met with a mouse in the stomach of a frog; all the soft parts of the limbs were gone, so as to leave only the naked bones, which were considerably wasted, and converted into a semi-gelatinous substance. (*Ibid. p. 102.*) Earth-worms enclosed in tubes were converted into a whitish pulp in thirty hours, in the stomach of the water newt; p. 104. He found numerous small white worms in the stomachs of three-fourths of all the newts he examined, from five or six in number to a hundred and more. These were so delicate that they would not bear even slight pressure; and thus afford a proof that nothing like trituration can go on in the stomach, but that digestion is simply solution by the gastric liquor; p. 104—111. In serpents the process occupied from two to five days. The tibizæ of frogs were almost completely dissolved in five days; § 118—122. As the animals swallowed by serpents often lie in part in the œsophagus, a question arises, whether they undergo any digestion in that tube, or whether this function be the exclusive attribute of the stomach. A viper, says Charas (*Descrip. Anat. de la Vipère*), vomited a lizard, which had been swallowed twelve days before. All the front of the body, which had been in the stomach, had merely

merely the bones remaining, while the other parts were nearly as perfect as if they had been swallowed the same day. Spallanzani confirmed this want of digestive power in the oëtophagus, by direct experiment; § 125. Naturalists, says this indefatigable inquirer, were already apprized of the tardiness of digestion in serpents. Bomare, in his *Dict. d'Hist. Naturelle*, gives an account of a serpent at Martinique, which retained a chicken in its stomach for three months, and did not completely digest it. "It is remarkable that flesh does not become fœtid from remaining long in the stomachs of these cold animals, which I had occasion to observe particularly in a viper. A lizard was retained in its stomach for sixteen days, at the end of which time it had no odour but that of the gastric juice. Yet such was the heat of the season, that another lizard, which I had placed in a close vessel, containing a little water, emitted an insupportable stench before the expiration of the third day; § 127. The gastric liquor of a snake approaches in colour to that of foot; it had the fluidity of water, and evaporated very slowly; it had both a salt and bitter taste, and was not inflammable. It strongly resembled the gastric fluid of other animals, and this resemblance extended to the odour, which was exactly like that of the corresponding juices of birds of prey; § 123.

The idea of Blumenbach, that the venom of the poisonous serpents supplies the place of mastication, and promotes digestion by some septic power, seems completely unfounded. It is a provision calculated merely for purposes of offence. Where is this septic power, or what supplies its place in the harmless serpents, and in all other amphibia?

The whole alimentary canal of the amphibia abounds with a viscid tenacious mucus, the abode of several genera of worms.

Blumenbach failed completely in very numerous and diversified attempts to cram frogs and lizards with madder root, and thus to produce in their bones that beautiful rose colour, which is so quickly produced in the mammalia of birds, when thus fed. *Specimen Physiol.* p. 31.

Absorbing Vessels.—This system has been very little examined by anatomists, probably on account of the minuteness of the tubes, and the consequent difficulty of injecting them. We have nothing to add to the account given by Hewson, who first described them in the *Philosophical Transactions*, 1769.

No lymphatic gland has been yet seen in a reptile: birds have none in their mesentery, but they are seen connected to the large lymphatics of the neck.

It has been asserted that the chyle is colourless, and hence anatomists have explained why the vessels were so long undiscovered. In animals which have white chyle, the appearance of this fluid through the transparent coats of the lacteals supplies the place of injection, and affords an easy method of demonstrating them. Mr. Hewson states that he saw white chyle in a crocodile.

The distribution of the lacteals (if that term may be employed where the chyle, instead of being like milk, is transparent) on the intestine of the turtle, forms one of the most elegant preparations in comparative anatomy. By fixing the injecting tube in a vessel near the intestine, and waiting with a little patience, the quicksilver will gradually find its way into the minute ramifications of the lacteals. The large trunks on the mesentery contain valves, so that we cannot succeed in filling the absorbents of the intestine from them; but the ramifications on the intestine itself are destitute of these folds, so that when once the quicksilver has reached the surface of the gut, it will run forward without any obstacle. The peritoneal surface of the gut is com-

pletely covered with straight parallel branches, running according to the length of the intestine. Its inner surface is no less thickly covered with lacteals of a different appearance. When dried it seems as if the quicksilver were contained in small cells, covering the whole internal surface of the intestine so completely, that the point of a pin could scarcely be placed between them. Mr. Hewson has particularly described this appearance, and was doubtful whether it ought to be referred to extravasation or not. But we are convinced, from frequent examinations of this cellular structure, that it is a part of the natural organization; because the cells are regular and uniform in their size and arrangement; no force is used in the experiment; and a real extravasation presents an appearance altogether different. The extent of the absorbing system, as demonstrated in this way, is beyond any thing we could form an idea of from injections in man or warm-blooded animals.

After leaving the intestine, the lacteals accompany the blood-vessels on the mesentery, running at their sides, and communicating across them. Each artery has two veins, and there is a lacteal or more at each side of each of the three vessels; so that their number considerably exceeds that of the blood-vessels. A coarse representation of them, on the mesentery, is exhibited in *Monro's Physiology of Fishes*, tab. 30.

Near the root of the mesentery the large lacteals anastomose, so as to form a net-work, from which several large branches go into some considerable lymphatics on the left side of the spine. These last can be traced downwards almost to the anus, and belong to the parts situated below the mesentery, and particularly to the kidneys. At the root of the mesentery, on the left side of the spine, the lymphatics of the spleen join the lacteals, and immediately above this union a sort of plexus or net-work is formed, which lies upon the right aorta. From this plexus a large branch arises, which passes behind the right aorta to the left side, and gets before the left aorta, where it assists in forming a large receptaculum, lying in front of that artery. The thoracic ducts arise from this receptaculum. From its right side goes one trunk, which is joined by that large branch which came from the plexus to the left side of the right aorta, and then passes over the spine. This trunk is the thoracic duct of the right side; for having got to the right side of the spine, it runs upwards on the inside of the right aorta, towards the right subclavian vein. And when it has advanced a little above the lungs, or within three or four inches of the subclavian vein, it divides into branches, which, near the same place, are joined by a large branch that comes up on the outside of the aorta. From this part upwards, those vessels divide and subdivide, and are afterwards joined by the lymphatics of the neck, which likewise divide into branches before they join those from below; so that between the thoracic duct and the lymphatics of the same side of the neck a very intricate net-work is formed. From this net-work a branch goes into the angle made by the jugular vein, and the lower part, or trunk, of the subclavian: this branch, therefore, lies on the inside of the jugular, whilst another gets to the outside of that vein, and seems to open into it a little above the angle between that vein and the subclavian. Into the above-mentioned receptaculum the lymphatics of the stomach and duodenum enter: they have numerous anastomoses, forming a beautiful net-work round the artery which they accompany. From this receptaculum likewise, besides the trunk already mentioned, which goes to the right side, arise two other trunks, nearly equal in size; one of which runs upon the left side, and the other upon the right side of the left aorta, till they come within two or three inches of the

REPTILES.

left subclavian vein; where they join behind the aorta, and form a number of branches, which are afterwards joined by the lymphatics of the left side of the neck: so that here a net-work or plexus is formed, as upon the right side. From this plexus a branch issues, which opens into the angle between the jugular and the lower part or trunk of the subclavian vein. In these net-works, formed by the lymphatics near their termination in the veins, this system in the turtle differs remarkably from that in birds. Hewson's Account of the Lymphatic System in Amphibious Animals, Philof. Transf. vol. 69. p. 198.

The Liver, which is divided in the mammalia into several lobes distinct from each other, and is more uniform in birds, is still less divided in reptiles. Often it has no division of lobes, but is merely irregularly fissured on its loose and thin edge. Its proportionate size, however, is more considerable than in the two classes just mentioned. Occupying usually the two hypochondria, it extends far backwards under the intestines, and is supported in its position by folds of the peritoneum, analogous to those which exist in the mammalia. Its colour is no longer that reddish-brown which is seen in the mammalia and birds; but it partakes more of yellow.

In the chelonians the liver exhibits a peculiar arrangement, being divided into two rounded irregular masses, of which the right occupies the same hypochondrium, and the other is connected to the small curvature of the stomach. They are united by two narrow productions of the same substance, in which the principal vessels pass. In the green lizard, the geckos, the dragons, the iguanas, it forms a single mass of various figure, flat or convex below, concave above. Its loose edge has two fissures in the dragon, dividing it into three lobes, of which the right is prolonged into a sort of tail. There is only one fissure in the geckos, and the right part is equally more extensive than the left. In the common iguana it is lengthened into a long appendix. In the crocodile and cameleon the liver has two very distinct lobes; and moreover, in the latter, a long appendix. It has only one lobe in the serpents, in whom it is long and cylindrical. Like other organs, it assumes in this order a figure corresponding to the elongated form of their bodies. There is one lobe only in the salamanders, but two in the other batracians.

Hepatic Canals.—The common trunk of these canals is usually separate from the cystic duct, and not inserted with the latter in the intestinal canal, in reptiles, as well as in birds. This has been observed in the chelonian and saurian orders, in several ophidians, and some batracians. Yet this arrangement is not constant. For, in the crocodile, where the hepatic is sometimes separate from the cystic duct, it sends at other times a branch to the gall-bladder, which is inserted a little above its neck, and is itself united to the cystic canal, not far from the intestine. The mouth of the common canal was distant from the pylorus, says Cuvier, o. 26 in a crocodile, whose whole intestinal canal was rather more than a metre (about 39½ inches) in length.

In the testudo græca the hepatic canal sends a branch of communication to the cystic canal, not far from the gall-bladder; but these two canals open separately into the intestine, though near each other; the former before the latter.

The Gall-Bladder has its fundus usually directed backwards. Its proportional volume is less considerable than in mammalia and birds; and it is more intimately connected with the liver than in these classes. In the testudines it is almost entirely concealed in the right lobe of the viscus; and is placed under the same lobe in the crocodile. Where the liver is not divided into lobes, the situation of this refer-

voir is marked out by a fissure. In the ophidians the gall-bladder is absolutely separated from the liver, and situated at the side of the stomach, near the pylorus, a short distance beyond the posterior extremity of that viscus. Its form is generally oval, but it approaches to the cylindrical figure in the iguana.

The connections of the cystic and hepatic canals have been already mentioned. The former remains generally distinct from the latter, by the side of which it is inserted into the intestine. Sometimes it receives the branches of the latter in succession.

The Pancreas is a conglomerate gland, as in mammalia and birds, and possesses the same structure (with some unimportant modifications of colour, consistence, lobular divisions, &c.) as in man. Its position and figure vary in reptiles. In several chelonians it is triangular. That of the Nilotic crocodile is divided into lobes: it is irregular in the ophidians, and situated on the right of the origin of the intestinal canal. In the frog its figure is equally irregular, and it is situated in the arc formed by the stomach towards the front. It is placed in the first curve of the intestine in the salamander.

There is either a single or double pancreatic canal. In the Nilotic crocodile, for example, there are two, inserted in the intestine after the biliary canals, while there is only one in the land salamander, the insertion of which precedes that of the biliary tubes.

The Spleen.—This is a viscus, of which the use is not hitherto understood. It exists in all the vertebral animals; but its importance seems to diminish as we pass from mammalia to birds, from the latter to reptiles, and from these again to fishes; at least, if we may judge from the successive diminution of its volume in these four classes.

Its figure varies considerably in this class. It is shaped like the kidney in the testudines; small and spherical in the frogs and toads; elongated in the salamanders, as well as in the saurian and ophidian orders.

The abdominal Cavity, Peritoneum, and its Processes.—The offices of this membrane, in covering and insulating the various viscera, confining them, by its continuations and folds, more or less closely to the sides of the cavity, and facilitating, by its smooth surface, their motions with respect to each other, and to the containing cavity, will convince us of the importance of the membrane, and lead us to expect that it should exist very generally. We, consequently, find it in all the vertebral animals. Generally white, delicate, and transparent, it is sometimes black in reptiles.

In this class, as in birds, there is no diaphragm, and consequently no distinction of abdominal and thoracic cavities. All the viscera are contained in one large cavity, and surrounded by one membrane. Geoffroy, however, describes some muscular fibres coming from the sternum, and fixed to a membrane covering the convexity of the liver, which seem like the rudiment of a diaphragm. Annales du Muséum, v. ii. p. 50.

In the chelonians, the membrane produces certain subdivisions of the common cavity of the thorax and abdomen. We remark, 1st, the cavity of the lungs, which are continued far backwards, above the heart, liver, and intestines; 2dly, that of the heart, or pericardium, which touches the following behind; 3dly, that of the abdominal viscera, containing the stomach, liver, intestines, ovaries, testicles, and urinary bladder. In front it covers the liver, forming a sort of membranous diaphragm, separating it from the heart; and it closes the cavity of the pelvis behind. It also furnishes the mesenteric folds. The texture of this membrane appears stronger in the testudines than in other reptiles.

REPTILES.

The mesentery exhibits, in the different orders of reptiles, some varieties, which we shall shortly notice. The first fold, which is attached to the small intestine in the testudines, does not come immediately from the vertebral column, and does not form the mesentery properly so called, until after it has fixed the arch of the colon by means of a mesocolon. The duodenum is confined in the right hypochondrium, and loins, by laminæ of the common membrane, which cover it, and are then continued to the abdominal parietes. The mesentery of serpents is a narrow fold, not coming immediately from the vertebral column: the blood-vessels form numerous anastomoses between its laminæ, as in warm-blooded animals.

The saurians have a mesentery tolerably developed. The production, which goes to the large intestine, like that which belongs to the small, comes from the vertebral column. There is no transverse mesocolon.

Reptiles have no omenta; but structures apparently analogous to these fatty membranes occur in some of them. The serpents have membranous processes, containing much fat, and extending, like the great omentum of the mammalia, under the intestinal canal. Many saurians have also two productions of peritoneum, loaded with fat, advancing from the front edge of the pelvis under the abdominal viscera; there are fatty lobes attached to the testicles and ovaries of frogs. The latter are not regarded by Blumenbach in the light of omenta. "The yellow appendices," says he, (*ductus adiposi, appendices luteæ*), "which are found in the frog, on either side of the spine, and sometimes form one mass, sometimes are divided into several smaller portions, were considered by Malpighi as a kind of omentum. (*De omento et adiposis ductibus*, oper. t. 2. p. 35, &c.) That this resemblance is very remote, appears from several circumstances; and particularly from the constant and remarkable variations of size which occur in these parts at the pairing season." *Comparative Anatomy*, translated by Lawrence, p. 193.

These bodies, being apparently connected to the testicles and ovaries, are described with the generative organs by Swammerdam and Roefel. They consist of a pedicle, attached more particularly to the emulgent vein on each side, and of two, three, to seven or more pieces joined to it, varying in size according to the age and season. They are proportionally large in the tadpole. They may be seen small in female frogs, which have not yet laid their ova, although Roefel asserts that they increase in size with the generative organs. In this small state, Cuvier observes, that a vessel, filled with venous blood, and producing no branches, may be seen in the axis of each fringed portion. These vessels all join to form a common trunk in the pedicle; and this trunk terminates in the emulgent vein.

The absence of omentum in this class does not accord with its supposed use to keep the intestines warm. Is there any proof that the intestines are warmer with it, than they would be without it? And is there not as great a necessity for preventing the escape of heat in reptiles, or in birds, (which also have no omentum,) as in the mammalia? Cuvier observes, that many of the hibernating mammalia have two lateral omental appendices, which, with the principal omentum, are abundantly furnished with fat in the winter, so as to form "an adipous covering for the intestines, which no doubt contributes powerfully to retain their natural heat, to prevent the access of cold, and to supply the place of food." All reptiles are torpid in the winter, yet they have no omenta.

Urinary Organs.

The Kidnies.—These are distinguished from the same

glands in mammalia, and resemble those of birds and fishes, in the impossibility of distinguishing in them the two substances (see *KIDNEY*), and in the absence of infundibula and pelvis. Their situation, form, and relative size, vary in the different orders.

In the chelonians and saurians, they lie far back in the abdominal cavity. They adhere closely to the pelvis in the lizards properly so called, under the sacrum, and penetrate even under the tail; they go as far back, but they advance farther in front, in the salamanders. They lie altogether farther forwards, and very near each other, in the other batracians. In these three orders both kidneys are situated at the same height, and covered by the peritoneum on their inferior surface only. In the ophidians, the right is placed further forwards than the left; and they are connected, on each side of the vertebral column, merely by a prolongation of peritoneum, which surrounds and suspends them, without fixing them to the spine. There is a manifest relation between the peculiar arrangement, and the great mobility of the column in these animals.

Their form is short and thick in the chelonians, more or less elongated and flattened oval in the saurians and batracians, and extremely elongated in the ophidians. They consist, in the latter, of numerous separate lobes, placed in a chain one before the other. They are also minutely divided in the chelonians, at least on their two surfaces; for all the lobes are united in the centre. They form, on their surface, a kind of convolutions resembling those of the brain, and giving the glands a peculiar aspect.

Among the saurians, the crocodiles have them much divided, at least at a certain age. In a small crocodile, about a foot in length, Cuvier saw no division, while there were many in a larger individual of the same species. It would be singular if this should turn out to be a constant difference, as it is exactly the converse of that which exists in man. They are without lobes, or only slightly divided in other genera of the same order. They have no divisions in the batracians.

The origin of the ureters is analogous to that of birds; and their length varies according to the situation of the kidneys.

They end in the urethra in the chelonians, and the urine passes from that canal into the bladder.

They are short, large, and thick-sided in the crocodile, and pierce the superior surface of the cloaca, at a considerable distance from each other.

The principal ramifications of the urinary canals are easily seen in the ophidians, ending successively, as they come out of each lobe, in a common trunk, which follows the internal edge of the kidney, and forms the ureter. Arriving near the cloaca, each is dilated into a small oval bag, and then terminates separately.

In general they terminate in the cloaca or bladder, according as the latter reservoir exists or not.

Urinary Bladder.—Reptiles vary much in respect to the existence of this part. The chelonian and batracian orders have it: and it is found in the following genera of saurians; viz. the iguana, tupinambis, cameleon, dragon, stello; while it is wanting in the crocodile, lizard, agame, gecko, other genera of the same order; and in the ophidians.

The bladder is very large, with thin sides and weak muscular fibres in the chelonians; and it has a more or less marked division at its fundus into two portions. A very short urethra opens on the inferior surface of the cloaca: its cavity presents two prominences on each side, of which the anterior is pierced by the orifice of the vas deferens, the posterior by that of the ureter.

The

REPTILES.

The bladder always receives the urine by its neck, or by a beginning of an urethra, which opens immediately into the cloaca.

There are two large membranous bags in the frog and toad, occupying the situation of the urinary bladder, generally considered as such, and so described by Blumenbach and Cuvier. Townson doubts whether they ought to be considered as part of the urinary apparatus. (See his *Traacts and Observations*, p. 66. tab. 3.) They have no connection with the ureters. Indeed it is very clear, that the latter tubes open on the superior surface; while these two receptacles terminate on the inferior surface of that intestine. They contain a pure water. Their size, which exceeds all ordinary proportion to the bulk of the kidney, renders it likewise probable that they are not receptacles of urine.

Renal Capsules.—The parts to which this name has been given, and which are found in the three first orders of reptiles, are still smaller in proportion, than in mammalia and birds, and are completely separate from the kidneys. In the chelonians they are connected to the emulgent veins. In the saurians and ophidians they lie in the fold of the peritoneum, which unites the ovaries and oviducts.

For a description of the fringed fatty appendices, which are found in the batracian order near the testicles and ovaries, and the vessels of which join the emulgent veins, see the account of the omenta.

Organs of Circulation.—The whole of nutrition is effected at one operation in zoophytes: chyle passes into the parts in proportion as it is made; in insects also it bathes them as soon as it is formed, and they appropriate it. In the superior animals, there is an intermediate operation: a particular fluid only, always moving in a certain system of vessels, immediately nourishes the parts; and this fluid is renewed by the chyle. The motion of this peculiar fluid, of this blood, is called circulation;—a process confined to the superior classes, that is, to the vertebral animals, the mollusca, the worms, and the crustacea.

There are two principal points for our consideration in the circulation; its agents, and the routes of the blood.

That part of the latter is particularly interesting, which conducts the blood to the respiratory organ. One of the chief purposes of the circulation is to conduct the blood constantly, in greater or smaller quantity, into an organ, where it may undergo the mediate or immediate action of oxygen; and, as the qualities of the blood depend much on the degree of force of this action, and in the modification which the blood receives from it, while all parts of the body, being nourished by this blood, partake of its qualities, it follows that the whole nature of an animal will be in some fort determined by the distribution of its circulating organs, and by the route which this distribution marks out for the blood.

Hence arises the importance of the structure of the heart, in reference to natural history, and the correctness of the characters drawn from it for the formation of classes. Men of genius had foreseen, rather than demonstrated this importance; but it has been established on rational principles only in modern times.

The circulations through the body and the lung are called, respectively, the great and the minor. In the former, all the blood returning from the body by the *veins*, which joining together from all parts, ultimately end in one trunk, goes again to these parts by the *arteries*, of which a common trunk is gradually divided and sub-divided, until the last divisions, as well as their union with the roots of the veins, escape the eye.

If the common trunk of the veins communicated directly

with the common arterial trunk, there would be a single circulation; the blood brought back to the centre, would be sent again immediately to the parts, to return again directly, and so on; but this never takes place entirely.

Before the blood, brought back to the common trunk of the veins, can again enter that of the arteries, it must be sent in part, or altogether, to the pulmonary organ, in order to undergo the action of the atmosphere.

If the circulating organs be so arranged that every drop of the blood goes through the lung, by the minor circulation, before it can enter the arterial trunk, the common trunk of the veins of the body sending all its blood into the pulmonary arterial trunk, whose ultimate ramifications communicate with veins united into a common trunk, sending all its blood into that of the arteries of the body, there is a *double circulation*.

If, on the contrary, the common trunk of the general veins, instead of being distributed entirely to the lung, should only send to it a branch, while the rest of its blood should go directly into the common trunk of the general arteries, the minor circulation would be only a fraction of the great, more or less considerable, according to the size of the branch devoted to it. In each circuit of the blood, respiration would be exercised on a part only of this fluid, and the rest would go again into the body by the arteries, without having passed through the lung. This blood, and the parts nourished by it, would participate less, *ceteris paribus*, in the qualities which respiration could impart to it. This is what takes place in reptiles; their pulmonary circulation is only a fraction of the great, more or less considerable in the different genera. The other classes, *viz.* the mammalia, birds, fishes, mollusca, and worms, have a double circulation, and no part of their blood can return into the great, until it has gone through the minor circulation.

Yet we are not to conclude that the ultimate effect of respiration is the same, because circulation is the same. The mode of respiration may be different, and, as this is one of the factors, the product will be affected by its alteration. All the animals last enumerated have an entire pulmonary circulation, while, in reptiles, it is only a fraction: let them be, for example, as 1 to $\frac{1}{2}$. Now fishes, mollusca, and worms, breathing in water, and that oxygen only, which is mixed and contained in this water, may be considered as having a half-respiration, while reptiles, breathing air itself, have an entire one. An entire respiration, multiplied by a half-circulation, and a half-circulation by an entire respiration, give the same product; which is, in both cases, a half-oxygenation of the blood, using this term merely to express the changes taking place from breathing.

Mammalia have an entire circulation and respiration; and consequently an entire oxygenation. The quantity of the latter is even greater in birds in consequence of the peculiar manner in which air is introduced into all parts of their body.

The fraction of $\frac{1}{2}$ is only adopted for the purpose of illustration; the quantity probably varies in the different genera of each class, and cannot be rigorously appreciated.

By these considerations we may estimate, and in a manner calculate, the nature of each animal. As respiration gives to the blood its heat and energy, and through its medium imparts excitability to the organs, its quantity will determine the degree of vigour in the animal functions. Hence we deduce the great force of the moving powers, the acuteness of the senses, the rapidity of digestion, and the heat of the passions in birds. Hence the more moderate degree of all these in the mammalia; hence the inertness, the inactivity, and apparent stupidity, of the other classes. Hence, too, the various modifications of vital temperature natural to

REPTILES.

each of these classes, which are in an exact ratio to the degree of their other qualities.

The circulation is effected by means of muscular powers, which are applied particularly to the arterial system; the venous seeming to be merely passive. A hollow muscle, called a *ventricle*, possessing great and continued irritability, and contracting forcibly on the blood whenever it arrives, is placed at the union of the venous and the corresponding arterial trunk. Valves are placed at its two openings; one valve allows the blood to enter, and prevents it from going back again, while the other permits its exit, and cuts off the return. The ventricle then cannot contract without distending the arteries, pushing forwards the blood, which they contain already, and thus producing the *pulse*. The ventricle, having expelled the blood which irritated it, is relaxed and dilated, and then immediately filled with a fresh quantity of blood from the veins. Before entering the ventricle, the vein is dilated into a muscular sac, called the *auricle*, with much less considerable muscular sides. This is irritated by the blood received from the vein, contracts on it, and sends it into the ventricle. It is hardly necessary to add, that the auricle and ventricle contract alternately.

Animals with a simple circulation have a single ventricle; but they possess sometimes two auricles. When the circulation is double, there may be a ventricle at the origin of each artery, or at that of one only. Mammalia and birds have two, and the *sepix* among the mollusca.

All other animals have a ventricle at the origin of one only of the two arteries, but not of the same in all. It is placed, in fishes, at the origin of the pulmonary artery; in the mollusca at the origin of the artery of the body, or the *aorta*, which is the name of that artery.

The union of the auricle and ventricle constitutes the *heart*. We find, therefore, in fishes and mollusca, a simple heart, *pulmonary* in the former, *aortic* in the latter. Reptiles, also, have a simple heart, at once pulmonary and aortic. Mammalia, birds, and *sepix*, have a double heart, or rather two, a pulmonary and an aortic, hearts.

In mammalia and birds the two hearts are united, and form one mass, which commonly bears the name of heart, as if it were a single organ. This is not the case in the *sepix*. See VERMES, in *Comparative Anatomy*.

We may now understand what naturalists mean, when they say that mammalia and birds have a heart with two auricles and two ventricles; reptiles and fishes a heart with a single auricle and ventricle. The latter phrase, besides comprising, in a common expression, two things really very different, contains also an error of fact; for many reptiles have two auricles.

Respecting the hearts of mammalia, birds, fishes, and mollusca, see the articles MAMMALIA, BIRDS, FISHES, and VERMES, in *Comparative Anatomy*. For the physiology of the circulation, the powers and actions of the heart, and the other organs concerned in it, see CIRCULATION and HEART.

The essential structure of the heart is the same in all animals; there are only modifications of greater or less importance. It is covered externally by a smooth membrane, the reflected portion of the pericardium; its cavities are lined by another smooth membrane, continuous with the linings of the blood-vessels; and there is more or less muscular substance interposed between them. The existence of the pericardium is as general as that of the heart; its nature and disposition are for nearly alike in all animals, that it is not worth while to notice the modifications.

Of the Heart.—In the different orders of reptiles, the heart is found to vary in some parts of its structure; there is,

however, no essential difference, when viewed in relation to its functions. The three first orders have a heart consisting of two auricles and a single ventricle, which is sometimes divided into many cavities, communicating with each other. On the other hand, in the batracians there is but a single auricle and ventricle, with its cavity of a simple form. We shall enumerate successively the differences of structure in the four orders of this class of animals.

First in the chelonians. In the animals composing this order, the heart has a form altogether peculiar. The length of the organ is much exceeded by its breadth; in some instances, it resembles the segment of a sphere; in others, it is of a square but elongated form, and curved in its longitudinal direction. In its natural situation, it is found beneath the lungs, in front of the liver, and partly between the two lobes of the latter. The pericardium, which is capacious and strong, is in contact with the membrane investing those organs, and is as firmly adherent to it as the pericardium is to the diaphragm in man.

The magnitude of the two auricles is much greater in proportion, than in any animals of the classes of mammalia or birds; the capacity of each is at least equal to that of the ventricle; they are situated in part above the latter, projecting upon its lateral and anterior parts. They possess somewhat of a rounded form, are without any appendix, and have their parietes thin, with some fleshy fasciculi in their structure. The right auricle, which exceeds in a trifling degree the size of the left, receives, by a single opening at its upper part, the blood returning from the body. Two valves are placed around the borders of the opening, giving it the appearance of a simple suture. The pulmonary veins alone terminate in the opposite auricle; their termination is provided in the same manner with two valves. A simple membranous partition separates the cavities of the two auricles and their openings into the ventricle. It is on the ventricle that depends the form which we have described as belonging to the heart. Its cavity is very small in comparison to its size, which is owing to the great thickness of the parietes. These are found to be composed exteriorly of a moderately thick layer of fibres, which have a direction parallel to the external surface of the ventricle. Beneath these, there are other numerous muscular fasciculi, varying in their direction, but proceeding principally from the superior to the inferior surface; the greater number of them are only contiguous, or separated from each other, allowing the blood to pass through the intervals formed between them as through a sponge. It results from this structure, that the cavity of the ventricle is diminished to one-third of its volume; it occupies the middle and right side of its base. In its greater part, it is lined by a continuation of the membranous fold which covers the auricular orifices, performing to them the office of a valve; it is of a square form, attached at the middle of its external surface to the partition between the auricles, and by its superior and inferior sides to the corresponding parietes of the ventricle; it is only loose and unconnected in its right and left borders. The first is extended over the opening of the auricle on the same side, and the latter over that of the opposite auricle; so that these openings appear in the ventricle separated by the breadth of the fold, while in the auricles there is but the thin septum intervening between them. The blood returning from the lungs into the left auricle is directed into the ventricle by means of the valve belonging to the former, in a course directly contrary to that leading to the opening belonging to the arteries of the body. It must, therefore, necessarily pass through the whole cavity of the ventricle, from the left to the right, and

REPTILES.

and into the intervals of the muscular fasciculi composing the parietes. From this structure it results, that there must be an admixture in the ventricle between the blood returning from the lungs, and that portion which has not been submitted to the influence of the surrounding element in its passage through those organs. The opening between the right auricle and the cavity of the ventricle is in a situation immediately directed towards the two cavities leading to the pulmonary arteries and arteries of the body; they are both situated completely to the right, in the cavity of the ventricle. The first, which is not always of the same magnitude, is placed inferiorly to the other, having a wide communication with it. In some instances the opening is extended very far towards the posterior part of the heart; in others it is so small, as in the land tortoises, that it does not exceed the diameter of the cavity leading to it. It is only in the first conformation, of which we find examples in many of the sea tortoises, that the appellation of pulmonary cavity can be applied to it. The blood arriving from the right auricle pursues a direction more particularly towards that part, by a channel leading from the one to the other. There is but one opening leading from the pulmonary cavity, which is that of the pulmonary artery; it is provided with two valves, and penetrates the base of the heart more inwardly than the openings to be next mentioned. These are the terminations of the two aortæ, which are found near to each other on the right side of the superior cavity, the same which receives the blood of the two auricles. The termination of the left aorta is situated a little more inwardly than that of the right, and inferiorly to it. They are each provided with two semicircular valves. This is the structure found in the sea tortoise; but in the land species the arteries of the body arise by a single opening from the ventricle. The heart of the turtle is best delineated by Mery, in the Acad. des Sciences, 1703.

In the second order of reptiles, the saurians, we shall commence with a description of the heart of the crocodile, which presents an example of the most complicated structure that we have found in the animals of this order, or even in the whole class of reptiles. The pericardium is found, as in the chelonians, adhering to the peritoneum investing the convex surface of the liver. The apex of the heart is connected by a very strong tendinous chord to the loose part of that bag, which is extremely thick, and has a fibrous structure externally. In its natural situation the organ is found occupying the space between the two lobes of the liver and the lungs on each side. The size of the auricles is somewhat less than in the chelonians; in other respects they are similar. The parietes are strengthened by fleshy fasciculi proceeding in different directions. The ventricle presents an oval form, and has its parietes of great thickness. Its cavity is divided into three compartments, communicating by numerous openings. One of these divisions is situated inferiorly and to the right. The auricle of the same side projects into its anterior part the blood received from the veins of the body by a wide opening, which is provided with two valves. The termination of the left descending aorta is found in the same cavity, in its left and anterior side. Behind this latter opening is seen an orifice, which leads into the smallest of the three divisions, at the middle of the base of the heart, and in which is found the common trunk of the pulmonary arteries. It results from this conformation, that there are two channels offered to the blood which has passed from the right auricle into the cavity of the same side; the one by the left descending aorta; the other into the cavity leading to the pulmonary artery. It may even take a third route, and pass through the numerous

holes which penetrate the partition separating the superior and left cavities. The left auricle projects into the latter the blood received from the pulmonary veins. A membranous valve is found attached to the border of the opening on its right side. The trunk common to the right descending aorta, carotids, and axillary arteries, is situated to the right of the valve. The blood must either pass into the arterial trunk, and from thence be distributed to the head and extremities, or penetrate into the intervals between the fleshy fasciculi of that cavity, and from thence into the two others. It results from this structure, that the blood distributed to the anterior parts by the carotids and axillary arteries, to the posterior parts by the iliacs, and to the tail by the middle sacral artery, is nearly all derived immediately from the lungs, whilst a portion of that which is distributed to the other viscera by the left aorta comes from the right cavity and from the auricle of the same side, and consequently has not been modified by its passage through those organs. The pulmonary blood is not so intimately admixed with that from the body, as in the chelonians. Such is the structure of the heart in the crocodile of the Nile, and the caiman or American alligator. For a view of the crocodile's heart, see Cuvier Leçons, t. 5. pl. 45.

It is less complicated in the common iguana (*iguana delicatissima*). In this animal, the situation of the heart is very remote from the liver, beneath the origin of the lungs, and in the most projecting part of the chest. It is of a conical form, being very broad at its base, and acute at its summit. The auricles present nothing remarkable. In the ventricle, there are but two cavities, the one situated to the right, which forms the proper cavity of the ventricle, the other to the left and superiorly, appearing as a sinus of the former. The openings of the pulmonary auricle and right descending aorta are found in the latter, nearly in the same manner as in the crocodiles. The opening of the right auricle is situated towards the middle of the great cavity or that of the ventricle, and is provided with a femilunar membranous valve, in the same way as that of the left auricle. The orifices of the pulmonary artery and left descending aorta are placed lower down in the same cavity; the first on the left, the other on the right. There is no pulmonary cavity. The interior of the ventricle is furnished with fasciculi of fleshy fibres.

The structure of the heart in the third order of reptiles, the ophidians, differs but in a trifling degree from that of the saurians, possessing the most simple conformation of this organ. There is no distinct pulmonary cavity. The auricles are of considerable size; that which receives the blood from the body is the largest. Their parietes are thin and transparent in the intervals between the fleshy fasciculi, by which their strength is augmented, and which are irregularly interlaced together. Their cavities are separated by a membranous partition. The figure of the ventricle is generally that of an elongated cone, irregularly formed in consequence of an appendix of the same figure, which projects from the left side beyond its base. The interior is divided into two cavities, the one superior, the other inferior, the former being extended into the appendix. An imperfect septum intervenes between them, having a loose unconnected edge on its right side, and is extended horizontally from the base to the apex; it is composed of fleshy fasciculi, allowing the blood to penetrate in their intervals. A considerable opening, by which the two cavities communicate, is found towards the right side of the base of the ventricle, at the part where the septum terminates. The parietes of the ventricle, of themselves moderately thick, afford attachment to a multitude of fleshy fibres, giving additional

additional strength, but greatly diminishing the cavity of the ventricle. These fasciculi are mostly separate from each other, allowing the blood to permeate between them as through a sieve; thus effecting the more perfect admixture between the portion arriving from the lungs and that from the body. The openings of the auricles are found close to each other, at the middle of the base of the heart, above the septum. Each orifice is closed by a semicircular valve of a membranous structure, the loose edge of which corresponds to the auricle of the same side. The termination of the arteries is found in the right side of the base of the organ; that belonging to the pulmonary artery is situated towards the left and in the lower part, corresponding to the inferior cavity. On the left of the latter is found the opening of the left aorta, corresponding to the same cavity, and placed opposite to the opening which forms the communication between the superior and inferior cavity. The opening of the right aorta is found immediately behind the last, and corresponds more particularly to the superior cavity, in which is received both the blood from the lungs and that from the body; the two portions united are projected partly into the right aorta and partly into the inferior cavity, and from thence into the left aorta and pulmonary artery.

In the fourth order of reptiles, the batracians, the heart presents a structure the least complicated of the whole class. It consists of a single auricle of a rounded figure, broader than the base of the organ, with its parietes strengthened by fleshy fasciculi. At the base of the auricle is the orifice of communication with the ventricle, which is single, having a simple cavity, with fleshy columns, not separated from each other. At its base is found the common trunk of the arteries, arising by a single orifice, situated more to the right and lower down in the ventricles than the opening of the auricles. The heart of the frog has been delineated by Swammerdam, *Bibl. Natur.* tab. 49; and by Roefel, *Histor. Ranar.*

Of the Blood-Vessels.—The distribution of the blood-vessels in the four orders of reptiles is varied according to the structure of the heart, and many other circumstances in their organization. In the batracians the arrangement differs in the greatest degree from that of mammalia and birds. All the arteries arise by a single trunk; consequently there is but one opening in the heart. In the three other orders, there are at least two openings, frequently three, which give origin to as many distinct trunks, one of which is destined exclusively to the lungs.

Of the Arteries in the Chelonians.—The arteries of the body arise from the heart by a single or double trunk in different species; those of the lungs by a single trunk. They are firmly connected together for a short distance from their origin. The trunk of the pulmonary artery arises on the left, lower down than that of the body. It quickly separates into two branches, one of which proceeding to the right lung, turns from the left to the right, then advances forwards to arrive at the anterior part of the organ, where the insertion of the bronchus takes place. The other proceeds in a contrary direction, passing across the œsophagus, it arrives at the summit of the left lung.

The trunk of the arteries of the body takes its origin at the right extremity of the base of the heart, and divides almost immediately into two great branches, the right and left posterior aortæ. When the trunk is double at its origin, they separate, forming these two branches. The right aorta furnishes, near its origin, another considerable artery, which may be denominated the anterior aorta. This soon divides into two branches, each of which is again subdivided

into two others, the internal of which, the smallest, is the common carotid, and the external, the subclavian or axillary artery. The common carotid proceeds by the side of the neck, concealed by the muscles going to the os hyoides, sending branches to the œsophagus and adjacent muscles. It arrives at the head, to the parts of which it is ultimately distributed, without dividing previously into two principal branches analogous to the carotids of mammalia. The subclavian or axillary artery furnishes nearly the same branches as the arteries bearing the same name in mammalia, with the exception that there is no branch corresponding to the inferior thyroid. The continuation of the trunk forms the brachial artery. The two posterior aortæ proceed on each side upwards and outwards; then bending backwards, they approximate again, and are connected by a communicating branch, which the left aorta gives to the right; nearly opposite to the fifth dorsal vertebra.

The right aorta, previously to communicating with the left, furnishes many arteries to the back or upper shell, corresponding to the intercostals. The left aorta furnishes considerable arteries to the viscera of the abdomen, which consume great part of its blood. When the trunk arrives beyond the cardia, it divides into three branches; the first, which is the smallest, furnishes a branch to the œsophagus, and then is distributed to the stomach. It is analogous to the coronary stomachic of mammalia. The second, almost as considerable as the trunk from which it proceeds, distributes arteries to the intestines, spleen, pancreas, and liver, in the following manner. The hepatic artery is the first given off on the right side; it turns backwards and downwards to arrive at the liver, and divides into two branches, near the base of the viscus, from one of which proceeds a small branch to the pancreas, and numerous others to the duodenum. The second branch is one of small size, and is distributed to the second turn which the colon makes to the right. It is the colica dextra. The third branch passes from the right to the left, and distributes its branches to the transverse colon. It is the colica media. After having given off these branches, the trunk pursues a short course between the layers of the peritoneum, in a direction downwards and backwards. It then distributes the following branches. The pancreatic, which passes from behind forwards upon the left border of the pancreas. The splenic, a very small artery, distributed exclusively to the spleen. A very considerable branch, belonging to all the right part of the colon and cæcum. It is a second colica dextra. A small artery, which, after having given a branch to the cæcum, proceeds to anastomose with the next, the proper mesenteric artery, which is larger than any of the preceding, and ramifies in the mesentery of the small intestine, to which it is ultimately distributed. Lastly, the third branch, resulting from the division of the posterior left aorta, the second in magnitude, proceeds obliquely to the right and backwards, and anastomosing, as has been mentioned, with the right aorta, without furnishing any branch. The common trunk, formed by their union, appears rather as a continuation of the right aorta; it extends along the vertebral column to the pelvis, giving off the following branches in its course. Five or six small branches on each side, corresponding to the intercostal or lumbar arteries. The spermatics. One or two branches on each side to the kidneys. A small artery corresponding to the posterior mesenteric, which is distributed to the cloaca.

The common posterior aortic trunk terminates by four branches, in the individuals belonging to the testudo græca, which we have dissected. The first on the left was the external iliac of that side, then came the internal iliac of the same

REPTILES.

same side, and opposite to it the primitive iliac of the right side. Between the two latter arose the artery of the tail, corresponding to the middle sacral artery. The branches of the internal iliacs are very analogous to the same arteries in mammalia. The trunk divides into two branches; one sending branches to the bladder and cloaca; the other dipping into the pelvis, and corresponding to the ilchiatic and posterior iliac arteries. The external iliac proceeds forwards upon the border of the pelvis, furnishes an analogous branch to the epigastric, from which arises the anterior iliac. The first descends upon the internal and inferior parietes of the upper shell, and passes in a direction from behind, forwards. A second branch, which arises from the external iliac, opposite to the epigastric, descends along the anterior border of the pelvis, as far as the symphysis of the pubis, and is lost in the muscles of that part. After having furnished these two arteries, the external iliac passes out of the pelvis, takes the name of crural artery, giving off first the circumflex arteries, then the profunda, and in the rest of its course is analogous to what it is found in mammalia.

The distribution of the principal arterial trunks in the saurians differs but little from that which has been described in the preceding orders.

In the crocodile there are three arterial trunks, each having a distinct opening in the ventricle, provided with two semi-lunar valves. The pulmonary artery, which arises from the cavity bearing the same name, is situate to the left, and somewhat superiorly; the posterior left aorta, which arises from the right and inferior cavity, and is situate between the pulmonary trunk and the next to be mentioned; the posterior right aorta, corresponding to the superior cavity. These three trunks are connected together for a short distance from their origin. From the latter proceed, in the first place, the trunk common to the subclavian and left carotid, which remains attached for some extent to the posterior left aorta, then advances obliquely forwards, passes beneath the bronchus, and divides beyond that canal. Secondly, a similar trunk for the same arteries on the right side. The posterior aorta, after having given off these branches, turns in a direction, first from below upwards, then from before backwards, and divides in a direction obliquely inwards beneath the spinal column, without furnishing any remarkable branch until it receives the communicating branch from the left aorta. This latter turns around the bronchus on its own side, and passes backwards and inwards in the same way as the preceding. After having passed the cardia, it divides into many branches, which proceed to the stomach, spleen, pancreas, and duodenum. These receive the greatest part of the blood of the trunk. The latter has no communication with the right aorta, but by an artery, the diameter of which is scarcely equal to a fourth part of the trunk from which it proceeds.

We have already alluded to the consequences resulting from this arrangement of the arteries, in the description of the heart. All the other arteries derived ordinarily from the abdominal aorta, with the exception of the cæliac trunk, here take their origin from the right posterior aorta. It is remarkable that the anterior mesenteric takes its origin at a very considerable distance from the cæliac trunk, or from the arteries ordinarily composing it; while, in the chelonians, it most frequently arises very near, or is even a branch derived from it. The splenic is also given off by the cæliac. After having passed through the substance of the spleen, from its anterior to its posterior part, and distributed to its substance many small branches which arise at a right angle from the trunk, it passes out almost as large as at its entrance, and proceeds to be distributed to the rec-

tum, and the termination of the small intestine; that branch of the splenic having the latter distribution, forms a considerable communication with the anterior mesenteric.

The pulmonary artery, very soon after its origin, divides into two branches, which proceed to the lungs, in the same manner as in the chelonians. Their diameter is nearly equal to that of the trunks formed by the carotids and subclavians on each side.

In the common iguana, which has the heart placed very far forwards in the chest, the arteries of the body have, in the same manner, two distinct trunks arising from the two cavities of the heart, although they are united at their origin. The left posterior aorta does not furnish any branch before it becomes united to the right. The latter gives origin to the carotids and subclavians, as in the crocodiles; but with this difference, that the latter do not arise from the same part as the former, but much farther backwards, on account of the heart being placed so much anteriorly.

In the lizards properly so called, the two aortæ advance forwards out of the chest; the right having first divided into three branches, the left without forming any division. The latter turns backwards upon the sides of the neck, to proceed afterwards along the vertebral column; and at the point where it takes a direction from before backwards, it receives the left branch of the right aorta, which forms a curvature in front of it. From its convexity arises the left carotid. The two other branches of the right aorta turn backwards, and unite in the same manner on the right side of the neck, forming two arches in front of each other. The carotid of the same side arises in a similar manner from the anterior arch, formed by the middle branch. The subclavians arise from each aorta a little before their junction. We have seen that in the crocodiles and the common iguana, they are produced both by the right aorta. The trunk formed by the union of the two arteries, which unite speedily after their origin from the heart, produces the different pairs of intercostal arteries in succession. It gives off, near its commencement, an artery to the œsophagus; farther on, a small artery which proceeds to the liver; and still farther, an artery which quickly divides into two branches; the anterior of which distributes its ramifications to the stomach, spleen, pancreas, and duodenum. The posterior belonging to the intestinal canal is properly the anterior mesenteric. From the trunk the following arteries next proceed: the lumbar, the spermatic, the posterior mesenteric, which proceeds immediately to the rectum, the renal, which are among the last given off, since the kidneys are situate very far back in the abdominal cavity. Lastly, it produces the iliacs and middle sacral artery. The latter is of so considerable a size, that it may be regarded as a continuation of the aortic trunk, of which the iliacs appear only as branches. This circumstance evidently depends on the great size of the tail, in comparison with the extremities.

The distribution of the principal arterial trunks in the third order of reptiles, the Ophidians, becomes much simplified from the deficiency of extremities, and there being but a single lung. The number of the trunks is the same; the relations between their openings in the heart have been already mentioned in the description of that organ. The pulmonary artery ascends and turns backwards upon the base of the heart, and speedily arrives at the inferior surface of the lung, where it passes from before, backwards to the left of the vein. The right aorta ascends on the same side, bends backwards, passes above the œsophagus, and obliquely backwards and inwards, to join itself to the left aorta, some distance beyond the point of the heart. It gives off, near its origin, some small arteries, which proceed to an orbicular

REPTILES.

orbicular gland, placed in front of the base of the heart, likewise to another gland of a more considerable size and elongated form, situate beneath the jugular. The trunk then furnishes the common carotid, the only one existing in this order of reptiles. It passes obliquely to the left, and advances, by the side of the left jugular, between the trachea and the œsophagus, and lastly beneath the latter. It sends a great number of ramifications to these organs, and divides near the head into many branches distributed to the adjacent parts. Near to the vertebral column, the right aorta produces a considerable branch corresponding to the vertebrae and superior intercostals which proceeds along the spine, sending to it branches, and wholly penetrating into it near the head. When the communication takes place between the right and left aorta, the diameter of the former is become very small, so that the greatest part of the blood which it has received from the heart is distributed to the parts in front of that viscus: it is properly the anterior aorta. The left aorta ascends and turns backwards to the left, passes beneath the œsophagus; then by the side of and always beneath the lung, receiving the right aorta beyond the heart; and continuing to pass in a direction backwards, it gives off branches corresponding to the intercostals, likewise arteries to the viscera. Those branches proceeding to the stomach, pulmonary bladder, and liver, are detached successively from the aorta, as it proceeds backwards; thus there is no cœliac trunk. Nearly opposite to the pylorus, the aorta furnishes the anterior mesenteric, which proceeds parallel to the intestinal canal one half of its extent, sending to it branches. Farther backwards the intestinal canal receives three other small branches in succession, from the same artery: as it passes backwards, it also sends similar branches to the kidneys, ovaries, &c.; arrived at the lower part of the abdomen, it penetrates beneath the vertebrae of the tail and is lost in that part.

In the last order of reptiles, the Batracians, the aorta, which proceeds from the base of the ventricle, soon divides into two branches, which separate and pursue a very oblique direction from within, outwards and a little forwards. Each branch gives off a pulmonary artery, a common carotid, an axillary, a vertebral, and arteries corresponding to the intercostals; then turning backwards, and approaching its fellow, it speedily becomes united to it. The trunk formed by their junction gives off, first, the cœliac trunk, then all the other arteries which arise ordinarily from the abdominal aorta, presenting nothing worthy of remark.

Of the Veins.—In the *Chelonians* there are two posterior venæ cavæ, which pass through the liver on each side, and receive in their course numerous small hepatic veins. Immediately after their exit from the liver, they are joined by two anterior venæ cavæ, one on each side, or by the common trunk of the jugular and subclavian. They all terminate in the right auricle by an opening in the form of a fissure, provided with two valves; they do not terminate in the cavity of the auricle, but in a receptacle communicating with it. The pulmonary veins united in a single trunk terminate in an analogous receptacle, which opens into the left auricle; around the borders of the opening, there is placed a fleshy valve in the form of a half moon.

In the *Saurians* and *Ophidians*, there is but one posterior vena cava, and two anterior, that belonging to the left side passes across, and above the heart, in a direction from left to right, and terminates in the common receptacle by the side of the posterior vena cava. This receptacle, similar to that found in the chelonians, has in the same manner its entrance into the right auricle, in the form of a fissure,

and provided with two valves. In this order, likewise, the anterior venæ cavæ are more properly considered as the jugulars. They have also a double azygos, one formed by the intercostal veins in front of the heart, the other posterior to it. They both join the right auricle by the side of the right jugular. It appears that they are rendered necessary by the situation of the venæ cavæ, which is very remote from the vertebral column, and more inferiorly.

The pulmonary veins in the saurians are similar to those of the chelonians.

In the ophidian order there is only one, which terminates in the same manner in the left auricle. Its volume exceeds that of the artery, which we have not observed in the other reptiles.

In the batracians the veins have a distribution similar to that of the arteries which results from their terminating in a single auricle, in the same way as the latter arise from a single ventricle. There are two anterior venæ cavæ which receive the blood from the head, neck, anterior extremities, and from the veins analogous to the external mammary, which are very considerable, extending beneath the skin to the groins, and likewise a posterior vena cava, which receives the veins from the other parts, presenting nothing worthy of observation.

The blood-vessels of the tadpole are described in the account of that creature in the division concerning the generative functions; and those of the proteus and firen, in the separate description of those animals at the end of this article.

Physiology of the Circulating Organs.—The nature of the blood in reptiles, the points in which it differs from the corresponding fluid in other classes, its difference in the various orders and genera, its relations to the food and to the secretions and excretions, are so many interesting topics of inquiry, on which we have absolutely no information to offer. Chemistry does not yet appear to be sufficiently advanced for the successful investigation of these and similar matters.

We may observe, in the first place, that the reptiles of these climates at least, possess, in comparison with warm-blooded animals, a much smaller quantity of blood in proportion to their size: hence their muscles are whiter, and some of their viscera, particularly the lungs, which are loaded and gorged with such a profusion of blood in the warm animals, present in this respect an appearance altogether contrary in reptiles.

“I made an experiment,” says Blumenbach, “on the water salamander, (*Iacerta lacustris*, L.) of which I dissected twenty-four, adult, lively, recently taken in the early spring, and weighing together $1\frac{1}{2}$ ounce, in order to measure the quantity of blood they contained: I could preserve from the whole of the bodies of all, only two scruples and a half. This small quantity of blood is to the whole body as $2\frac{1}{2}$ to 36; while in an adult and healthy man the proportions are calculated at 1 to 5. Hasselquist observed the same circumstance of the small quantity of blood in proportion to the body, in the crocodile of the Nile.” *Voyage dans le Levant & en Palestine.*

It is also remarkable, that the arterial blood of our reptiles differs in external appearance in the smallest degree, if at all, from the venous, so that one can be distinguished from the other only by the situation and course of the vessels; while, on the contrary, the bright scarlet arterial blood of the mammalia offers so remarkable a contrast to the dark livid or purple venous fluid; unless when they have been for some time in a warm bath or other warm medium, when it appears from the elegant experiments of Dr. Crawford,

REPTILES.

ford, that the venous blood, becoming gradually less and less dark coloured, approaches more nearly to the vivid redness of the arterial stream. (See *Philos. Transact.* v. 71. p. 487.) Haller observed that there is no difference between the arterial and venous blood in the frog. (*Oper. minor.* v. 1. p. 183.) And Spallanzani noticed the same fact in the salamander or water newt: "avutasi egualità di diametro, il colore del sangue venoso e somigliantissimo al colore del sangue arterioso." De' fenomeni della circolazione, pag. 100. And again, "il sangue arterioso in nulla differisce dal venoso, sia nel colore, sia nella densità." P. 193.

In this circumstance reptiles resemble the fœtus of warm-blooded animals; in which, so long as it remains immersed in its uterine bath, we know that the arterial and venous bloods are of the same colour.

Yet all animals of this class are not alike in this respect. Accurate observers have asserted, that in the tortoise the venous blood is black, and the arterial crimson, as in the warm-blooded classes. (Caldesi, *Osservazioni Anatomiche intorno alle Tartarughe*, p. 60. Mery, *Hist. de l'Acad. des Sci. de Paris*, 1669, v. 2. p. 210.) This difference probably corresponds with the diversity of structure observable in the respiratory organs, which are calculated, in the different orders of reptiles, to admit of a more or less intimate exposure of the blood to the air in respiration.

The colour of the blood varies in our amphibia according to the state of their nutritive functions: it is paler when they have fasted, of a deeper red when they have been well fed. If, under the latter circumstance, it be drawn from a vein, and exposed to the air, it exhibits a bright florid redness as it forms the coagulum.

The component elements of the blood of amphibia, considered in a general way, seem nearly to resemble those of the warm-blooded animals, except that in the former, when examined alive, there are almost always seen bubbles of air mixed with their purple stream, performing, like the blood itself, the circulation, and dividing that fluid in the vessels into intervals, as the mercury is interrupted in a badly made thermometer. Redi and Perrault observed this fact in tortoises; Jacobæus in serpents; Daudin in the green lizard, frog, and salamander (*Hist. Nat. des Reptiles*, *Introd.* p. 184.); and Blumenbach in the amphibia of Germany. Now, although in certain states the veins may be very turgid, and elastic air may be found in them after death, nothing of this kind is ever known to take place in a healthy and strong individual. The air indeed is supposed in the mammalia to constitute one-thirtieth of the blood, but it is so dissolved, and so intimately mixed in the vital stream, that it can only be extricated and exhibited in its elastic aerial form by artificial means.

The phenomena of the circulation are common on the whole to the reptiles with the warm-blooded animals, and are very familiar in the former, since the wonderful circulating motion of the blood was not only first actually seen and described in frogs by the great Malpighi, but is also still examined to the present time in those animals. The branchiæ of the tadpole are very favourable objects for investigations of this kind.

As the circulation can be actually seen in these animals, we may inquire on this subject, whether the globules of the blood, entering the minute vessels, can be really observed to change their figure, and become oval instead of spherical. "In warm-blooded animals," says Blumenbach, "I have never heard or read that any one has seen such a change; and I certainly have never seen, either in the incubated chick, in which the circulation of warm blood may be most clearly and beautifully observed, particularly on the fifth and

following days, or in the frog or lizard, any oval globules: yet Reichel asserts that he has seen globules changed from spherical to oval in the mesentery of the frog, and has given an elegant plate in illustration of the fact. See *Experimenta de Sanguine ejusque motu*, fig. 3." Blumenb. *Specimen Physiol.* p. 10. He doubts, however, whether this change can be considered as a natural occurrence in the healthy circulation, or ought to be referred to the disturbance naturally following the sufferings of the animal.

The motions of the heart, consisting in our amphibia of a single auricle and ventricle, agree in the alternate contractions and relaxations of those parts, with the analogous succession of systolic and diastolic changes observable in the double auricles and ventricles of the warm-blooded classes.

A question was formerly raised, concerning this systole or contraction, whether the ventricles are really shortened, or experience merely a diminution of diameter? The former, says Blumenbach, has now been proved by the most careful observations both in cold and warm-blooded animals; he adds, that he has never seen it demonstrated more clearly, and beyond every suspicion of inaccuracy or mistake, than in the common snake (*coluber natrix*), in specimens of which, two yards long, from the woods of Germany, he has observed, and frequently demonstrated, a shortening of the ventricle equal to two lines. Blumenbach states further, that the ventricle is completely emptied in its systole, not the least drop of blood flowing back into it from the aorta, in the snake, frog, and toad, and also in the incubated chicken. But he does not venture to decide, whether the same thing occurs in man and the other mammalia, or whether the semilunar valves may intercept some drops of blood, which thus are made to flow back into the ventricle.

Reproduction.—As the nutrition and growth of parts, in the healthy state, are among the most important functions of the blood-vessels, so the reparation of injury, and the restoration of what is mutilated, constitute another very striking instance of their powers, and a very impressive example of those prerogatives, which belong exclusively to living organized beings. Although this power of reproduction, taken in its most extensive acceptation, cannot be said to be withheld entirely from any animal, several genera of reptiles possess it in a more remarkable degree than any of the other vertebral classes. There is an interesting account in the *Memoirs de l'Acad. des Sciences de Paris*, 1686, particularly of the restoration of the tail of lizards. Spallanzani, Bonnet, and Blumenbach, have employed themselves in researches on this subject. The former first called the attention of the public to it in his "Prodrómo di un' Opera da imprimerfi sopra le Riproduzioni Animali." Bonnet published his memoir on the reproduction of the limbs of the water newt in the *Journal de Physique*, 1777. His enquiries were again published in his "*Œuvres d'Histoire Naturelle*," t. 5. and there are three memoirs by him on the subject, translated into English, in Spallanzani's "*Traçts on the Natural History of Animals and Vegetables*," v. ii. The experiments of Blumenbach are contained in his "*Specimen Physiologiæ comparatæ*." The experiments have been made chiefly with the water newt; on the *lacerta agilis* of the terrestrial kind, see P. T. Hartmann, *dubia de generatione viviparorum ex ovo*, p. 26; respecting the lizards of the Antilles, see Oldendorp *Geschichte der Caraibischen Mission*, p. 97.

"It might be supposed," says Bonnet, "that the amputation of the limbs is most painful, and that the animals would suffer long and severely from it; however, one of my observations apparently infers the reverse. I cut the left

REPTILES.

hand and the right foot off a large newt; and a stream of blood, as thick as a hog's bristle, continued spouting out nearly two minutes without intermission. Not only did the animal seem not in the least enfeebled by the loss of blood, but, in scarcely a quarter of an hour, to my great surprize, it swallowed two earth-worms." Spallanzani's *Traacts*, v. ii. p. 367.

The following narrative is extracted as a specimen of Bonnet's experiments. "On the 6th of June I cut off the right arm and left leg of a large newt close to the body. (It seems from the accompanying figure that the sections passed through the femur and humerus respectively.) A stream of florid blood spouted a minute and a half from each wound; however, the vessels soon closed, and the newt was apparently as well as those unamputated. But it will easily occur, that it did not swim with equal facility. When about a month had elapsed, I began to perceive a papilla, of a violet grey colour, near the edge of the trunk or section. This was the origin of a new arm and leg, which gradually increased, and were quite perceptible, although still very small, on the 14th of July. The two papillæ grew more in length than in thickness: they became minute stumps, and on the 1st of August were two lines long. A kind of cleft hardly perceptible announces the appearance of two toes: no cleft appears on the originating arm. The new parts were very distinguishable from the old by their lighter colour. The two toes were easily recognised on the seventh: they were real miniatures, and truly most minute. The stump of the arm had increased, but there was no indication of fingers.

"It is pleasing to observe the little hand fully unfolding, while only three fingers of unequal length are visible: the middle one is the longest. The arm has made no sensible progress. The new foot had four toes also of unequal length; the first and second of which are longest; the other two only begin to appear; the fourth is scarcely perceptible. Evolution advanced every day. The regenerated members began to deepen in colour, so that the line, discriminating the old parts from the new, was no longer so conspicuous; but the black specks on the toes of unamputated newts were still imperceptible. On the 22d of August four well-shaped fingers were already on the hand; but only four toes out of the five which the foot regenerates; and they all have to acquire more size, consistence, and colour. I continued my observations on the daily evolutions of the members; and the following were their dimensions in length on the 30th of September.

Old Members.	New Members.
Arm - 4 lines.	Arm - $2\frac{1}{2}$ lines.
Cubit - $3\frac{1}{2}$	Cubit - $2\frac{1}{2}$
Thigh - 3	Thigh - $2\frac{1}{2}$
Leg - 4	Leg - $2\frac{1}{4}$
Longest finger $3\frac{3}{4}$	Longest finger $1\frac{1}{2}$
Longest toe - $4\frac{1}{2}$	Longest toe - $1\frac{1}{2}$

Even in the beginning of October, the fifth toe of the new foot was not visible." *Lib. cit.* 372, et seq.

There is a kind of semi-transparency in the reproduced parts, which the original members have not. This continues long, and changes slowly as the reproductions colour. The transparency is evidently greater on the edges of the fingers than elsewhere; if examined with a magnifier they seem inclosed in a fine diaphanous envelope: but nothing of this is evident in the old fingers. (P. 376.) "It is incredible how long the new fingers require to attain the size of the old. I have had newts, whose fingers, in thirteen months and more, were not as large as those of unamputated members."

(P. 393.) "When the tails of large newts were amputated near their origin, the whole died in a certain time. If the part be cut off about its middle, reproduction will follow. A tail was cut on the 11th of July, and on the 14th of August, the reproduced part was about three lines and a half long, and four and a half in diameter at the base. The new portion was ten lines in length on the 20th of September, and shaped exactly like the tail of a newt. I could observe no difference between the motions of this regenerated tail, and those of tails unamputated. On the 8th of October the regenerated part had a peculiar transparency, wanting in the rest of the tail." P. 381, et seq.

"The fingers and toes are not evolved in the same proportion as the arm and leg. Now, when I write this, on the 10th of October, the new arm and leg of the newt, mutilated on the 6th of June, have nearly attained the size of the original members, while the regenerated fingers and toes have not acquired half their natural size; yet they are perfectly well formed, and execute all their functions." P. 390.

Blumenbach found that the true salamander (*lacerta salamandra*) possesses the same reproductive power as the water newt (*lacerta lacustris*): that a third part of the tail, or a toe, would be perfectly but very slowly reproduced, and remained even at the end of a year considerably inferior in size to that of the original parts. Specimen p. 32.

Bonnet made other experiments to determine whether reproduced members possess the same powers of reproduction as those amputated. He cut off an arm and a thigh of a large newt on the 2d of June: as soon as the hand and foot were visible, he cut them off, and they were renewed: he repeated this four times, the last operation being on the 13th of October, and the parts were each time restored. P. 394, et seq.

He dislocated the arms of one and the thighs of another newt, so that the members immediately after were pendent, as if dead, the animal having no power over them. On the following evening each newt moved the disjointed limbs with a liberty and facility which announced that nature had already repaired the disorder. P. 431.

The most surprising fact in Bonnet's Memoir is the reproduction of the entire eye. "With a scalpel," says he, "I extracted the right eye of a large newt on the 13th of September, 1779; but I did not obtain the globe without much injury to the tunics. A deep bloody wound in the socket of the eye was the consequence of this cruel operation. And the reader will not be surprized if I hardly expected any thing from it, and that the newt would probably remain blind for ever. How great was my astonishment, therefore, when, on the 31st of May, 1780, I saw a new eye formed by nature. The iris and cornea were already well shaped, but the latter wanted its peculiar transparency, which is very considerable in these animals. The restoration was complete on the 1st of September; the cornea being transparent, and the iris having acquired its yellow gilded colour. On the 8th of November 1780, it differed from the other eye only in being a little smaller, and in the iris, or golden circle, going only half round the ball." P. 432, et seq.

"I repeated," says Blumenbach, "the experiments of the celebrated Bonnet, concerning the reproduction of the eye in the water newt. I cut out the whole globe, at the insertion of the optic nerve, in three instances, in neither of which was the organ reproduced: but a white and firm fungus, shooting from the cut end of the nerve, gradually filled the orbit, the animals themselves becoming affected with a kind of dropsical swelling, and dying in a few

few months. Instructed by these failures, I proceeded to operate in a different way on a fourth animal, in May 1784. I first divided the cornea, to let out the lens and other humours, and then cut away the remaining empty and collapsed coats, leaving a small portion of the common coverings of the bulb, which, from a careful examination in water with a glass of the parts removed, I judge to have been scarcely equal to one-fifth of the whole globe. In the following months the whole orbit seemed closed by the approximated eye-lids, which, however, began to separate in the sixth month after the operation, and thus disclosed a new little bulb springing up from the bottom of the orbit. This new globe was still much smaller than the other in April 1785, when the animal died accidentally, though in other respects it was most perfect, exhibiting the golden iris with its regular pupillar aperture behind the cornea, all which points are clearly distinguishable in the preparation which I preserve." Specimen, p. 31.

"On comparing," says the author last quoted, "the facts just detailed with the very limited and much less perfect reproduction observable in warm-blooded animals, we shall become sensible of the wide difference between them and the amphibia. I am daily more and more convinced, that no parts are reproduced in man and the other mammalia, except such as are composed merely of cellular substance, and enjoy no other kind of vital power except common contractility; and I cannot find sufficient proof that the irritable muscular fibre, the sensible nervous medulla, or those parenchymata which are endowed with a peculiar modification of vitality, have ever been truly reproduced in a warm-blooded animal." Ibid. p. 32.

Tenacity of Life.—This subject is so far analogous to that which we have just considered, that we pass naturally from the view of the facts, in which the surprising reproductive powers of the class is evidenced, to the no less astonishing examples of their very hardy vitality; of the energy and permanence of their vital forces, both in individual parts, and in the body at large.

The amputated tails of water newts, and the divided fragments of the blind-worm (*anguis fragilis*), exhibit very lively motions for ten hours and more. The heart of a frog or serpent continues to palpitate on irritation many hours after its separation from the body; and the limbs of frogs are excitable by the Galvanic influence for a long time. Some reptiles, as the serpents and testudines, can open and shut the mouth long after the head has been severed from the trunk. General Gage informed Blumenbach that he had seen the amputated head of a rattlesnake bite long after its separation: and another British officer stated to him that when he put a stick between the jaws of an American turtle, the second day after decapitation, it was firmly held.

The same energy of the vital force in the parts, and the independence of one class of functions on another, in the amphibia, are further evinced by many well known facts; the limbs of turtles have moved for eleven days, nay, on the thirteenth day after decapitation (Güldenstaedt, *Theoria virium corp. hum. primitivarum*, p. 74.); and a rattlesnake lived some days after the skin had been removed, and most of the viscera taken away. Tyson, in *Philosophical Transactions*, N^o 144.

In the beginning of November, Redi opened the skull of a land tortoise, and removed the whole brain. The animal did not seem to suffer, it moved about as before, but groping its way; for the eyes soon shut after losing the brain, and never opened again, a fleshy integument formed,

which covered the opening of the skull, and in this state the animal lived till May. Spallanzani deprived four frogs of the brain; two lived till the fifth day. He also deprived three newts of the brain; they suffered violent convulsions; their eyes closed, they hardly moved from one place to another; and expired about the middle of the third day. He cut the heart out of three newts; they took to flight, leapt, swam, and executed the same functions as before; however, all died in forty-eight hours. Four frogs, deprived of the heart, kept their eyes open, and preserved the use of their limbs. They survived thirty-six hours. Spallanzani's *Traacts*, Introduction, p. 45.

Captain Cook met with a turtle, in which there was a wooden harpoon about fifteen inches long, and barbed, between the shoulders. The opening by which it had entered was quite healed.

Redi and Boyle saw some signs of life in serpents after they had been twenty-four hours in vacuo. And they will live more than four hours in spirits of wine. See Daudin, v. 6. p. 100; and v. 1. p. 270.

In our account of the physiology of the digestive organs, we have already noticed the singular power which reptiles possess of remaining for such long periods without food. They are equally remarkable for being able to bear, permanently, considerable degrees of heat and cold. Not only are most of the class inhabitants of the warmest regions, but some of them, like some fishes, are known to live in warm springs, inhabiting them spontaneously, and appearing to be healthy. (See Cocchi in Spallanzani, *Opuscoli di fisica animale e vegetabile*, v. 1. p. 46.) They live in the warm springs of Pisa, which rise to 37° of Reaumur, 115° of Fahr.

"Besides a host of suspicious narratives," says Blumenbach, "of newts, and other amphibia, which have lived for a considerable time in the human body, there are many unexceptionable and indubitable examples of this remarkable phenomenon." See the narrative of Th. Reinesius, a most respectable authority, concerning a girl of Altenburg, in Bartholin, *Act. Havniens.* v. 2. p. 110; Harder, *Apiar. observat.* p. 89; I. R. Zwinger in *Act. Helvet.* v. 1. p. 22; *Hist. de l'Acad. des Sciences de Berlin*, 1770, p. 40; a mass of citations in Jacobæus de ranis et lacertis, p. 12; Paulini de Bufone, p. 38; I. Helwig *Observ.* p. 249 and 272; Kundmann *Promptuarium*, p. 108; also *Act. Natur. Curios.*; *Collectan. Vratislaviens.* et *Commerc. Literar. Noric. &c.* These facts are not so remarkable on account of the degree of heat to which the animal is exposed, as from the other concomitant circumstances. We must observe, however, that these animals inhabited the stomach so long as they continued alive, while the individuals troubled by these unusual guests were led, by their suffering, to drink copiously of water, and thus in a manner supplied the newts with their natural element.

"Reptiles have the power of bearing intense cold as well as great heat. I one morning found a tree-frog, which I had kept for some time, in consequence of a frost suddenly set in the preceding night so as to reduce the thermometer to 30° Fahr., completely inclosed in a cake of ice, like insects in amber; of course it was motionless, the eye-lids shut, &c. As the ice melted, the animal recovered, first moving its hind legs, when they were disengaged; the head and trunk still being most firmly detained; when the solution was complete, the whole animal was restored, seemed as well as before, and survived a long time. Du Fay attests the same circumstance concerning water newts; *Mém. de l'Acad. des Sciences de Paris*, 1729, p. 144. The amphibia are exposed to be frozen in their winter sleep; but we are the less

REPTILES.

surprised at the occurrence, because all the functions are either entirely suspended, or most languidly performed." Specimen, p. 10.

Organs of Respiration.—After describing the heart, and viewing the phenomena of the circulation, we proceed to the lungs, which are not only most important parts in the economy of all animals that possess blood, but constitute, in the peculiarity of their structure and functions, the most striking marks of distinction between reptiles and warm-blooded animals.

All reptiles breathe by means of lungs, which in their bulk considerably exceed those of the mammalia, while the latter are as far superior in the abundance of their vascular ramifications, and the wonderful minuteness of their internal subdivisions. These large, but loose and rare vesicular lungs, are contained, not in a particular cavity, separated from the abdomen by a diaphragm, but, with the other viscera, in a general cavity of the body. Hence the mode of respiration is as different from that of the mammalia, as the texture of the organ.

To the general position, that reptiles breathe by means of lungs, there is an exception in the batracian order; in some of which (the proteus and firen) there are branchial appendages or gills, as well as lungs; while in the first state (the tadpole) of others, there is a similar conjunction of these two modifications of respiratory apparatus. See the anatomy of the tadpole, in the account of the generative organs, and that of the firen and proteus, at the end of this article.

The Air-tubes.—The trachea is not divided into bronchi in the ophidian order, which have a single lung; neither does this division take place in the green lizard (*lacerta agilis*), whose trachea, having reached the united anterior extremities of the two lungs, opens into each by a large orifice: but it is found in almost all the other animals of this class. The division is effected very early in the chelonians, which have consequently a very short trachea, and long bronchi; more particularly because the latter, instead of entering the lungs directly, first make a turn in the chest. The trachea is divided much later in the crocodile, where the tube is bent from behind forwards, divided into bronchi, which also run forwards, and then turn from before backwards, remaining for some time joined to each other. The bronchi are extremely short in most other reptiles: they begin, in the batracians, immediately below the larynx.

Reaching the lungs, the bronchi generally terminate abruptly by one or more large orifices, which open into the cavities of these viscera. This is what occurs in the ophidians; but in the chelonians and the crocodile, each bronchus is continued into the interior of its lung, before it terminates. They are continued, in the testudo græca, into the most remote part of the lung, without undergoing any sensible change of diameter; and they communicate with the large cells composing these viscera, by ten or twelve wide orifices, of which the outlines are circular, like the commencement of canals. In the turtles, each bronchus penetrates in like manner to the farthest part of the lung, but gradually diminishing in diameter. Their sides are pierced with numerous holes, opening into the pulmonary cells.

The relative size of the trachea and bronchi does not exceed what we observe in the mammalia and birds, except in the ophidians, where the diameter of the former is very considerable. These air-tubes never exhibit any inequalities, such as are seen in birds.

They are generally composed of complete cartilaginous rings, and consequently are little susceptible of changes in size. We must, however, except the crocodile, in which

animal the front end of the trachea presents, on its upper surface, a membranous interval, which is wider the nearer we come to the larynx; (see Humboldt *Recueil d'Observations*, &c. tom. i. p. 11. of the crocodile of the Orinoco; and Geoffroy in *Annales du Muséum*, tom. ii. of the Nilotic species); the cameleon, where the annuli are incomplete in the last portion of the trachea, and at its bifurcation; and the ophidians, in whom the trachea possesses cartilages only in one third of its circumference. These cartilages are also visible for a short space along the front end of the lung, in a groove of its inferior surface, containing also the pulmonary vein. The trachea, however, ceases suddenly on touching the lung, and dilates immediately to form its sac.

In those reptiles which have bronchi running throughout the length of the lungs, the portion of the tube, contained in these viscera, has only imperfect and irregular pieces of cartilage, which nevertheless surround its circumference. They are more thinly scattered in the turtles, in proportion as we observe them farther back in the lung.

This cartilaginous structure of the air-tubes (the trachea and bronchi) of reptiles, renders them very incapable of changing their diameter. They seem entirely destitute of transverse muscular fibres; nor do we perceive any longitudinal ones to diminish their length. The membranous trachea of the ophidians, possessing cartilages only in the inferior third of its circumference, seems equally destitute of muscular fibres. On this membrane we discover a fine white and opaque net-work, which is continued into the interior of the lung, where its meshes, as we shall see, border the cells, and are formed of stronger threads, apparently of a tendinous structure, and perhaps capable of contraction.

Vesicular Structure of the Lungs.—We have mentioned that the lungs of reptiles are very large: they are immense in the testudines and cameleon, and are even considerable in the native amphibia of these climates, if you compare their relative bulk to that which they possess in warm-blooded animals. We have just seen that the bronchi do not divide, that they do not usually enter the lungs, but terminate abruptly by one or more large orifices, as soon as they have reached these viscera. In the batracians and saurians, the lungs form two sacs, varying considerably in their form and relative size, and having their internal surface divided by membranous plates into polygonal cells, in which other smaller plates form more minute divisions. They have been justly enough compared by Blumenbach to the reticulated structure, in the second stomach of ruminating animals. These cells are more numerous, smaller, and deeper in the anterior part of the sac: they become more open towards the posterior part; and when the latter terminates in one or more appendages, we see only a net-work, with loose and extremely fine meshes. Afterwards the parietes of the pulmonary sac are quite simple, and without any division. Such is the structure in the appendices which terminate posteriorly the lungs of the cameleon, and the agame or *lacerta marmorata*; and of the great bladder in which the single lung of the ophidian order ends.

The lungs of the salamander, the proteus, and firen, form also simple sacs without any division.

"In frogs and toads," says Blumenbach, "the lungs are made up of polyhedric and large cells: the same structure is observed in the *lacerta agilis* and salamander. They form an oblong bladder in the aquatic *lacerta* (water newts). The lung of the coluber matrix forms a single bag of large size, hollow throughout; and the same structure seems, from the reports of anatomists, to exist in other serpents. (See Coiter *Obs. Anat. Chir.* p. 126. Charas

REPTILES.

Nouvelles Obs. sur la Vipère, p. 39. Tyfon in Phil. Transf. N° 144, p. 30. tab. 1. fig. 1. tab. 2. fig. 4. Seba Thefaur. vol. ii. tab. 109. fig. 1—5.) The pulmonary bag of this coluber exceeds a Paris foot in length. Rather more than the anterior half has thick sides, with an elegantly reticulated internal surface, resembling in its general habit that of the internal surface of the second stomach of the ruminating mammalia. The remaining posterior portion is a simple thin membranous bladder." Specimen, p. 12.

The structure is rather more complicated in the chelonian order. Each of the openings of the bronchus, which we have stated to be about ten or twelve in the testudo græca, is the entrance of a particular sac, the sides of which are composed of polygonal cells, in which there are still smaller ones. Each of these cells is bordered by whitish and as it were tendinous chords, which appear designed to support their sides, and fix the sacs to the orifices of the bronchus. The sacs or principal cells are much smaller, and more numerous, in the turtles, and correspond to the numerous orifices with which the bronchus is pierced. We see also the cords forming and supporting the cells, and giving to the lungs of those animals the appearance of a cavernous tissue.

The form and size of the pulmonary cells may be somewhat different in the crocodile, but their essential structure is the same. In this respect the crocodiles depart from the lizards, and approach the turtle and tortoise. Geoffroy in Annales du Muséum, vol. ii. p. 46.

How different a notion do these details convey to us, of the structure of the lungs in reptiles, from that which they possess in the warm-blooded classes! Although they may be described in the latter as cellular, spongy, and light, yet, when compared to the same organs in the former class, they are vastly more compact, made up throughout of an infinite number of ramified air-tubes, and of countless most minute bronchial cells connected to them, united and interwoven with common cellular tissue. Hence, if we compare any mammiferous animal with a reptile of the same size, as the *vespertilio murinus* with the *rana bombina*, the lungs of the latter are indeed the largest, but are beyond all comparison inferior to those of the former in the very inconsiderable number of their cells.

As the lungs of warm-blooded animals so wonderfully surpass those of reptiles, in the minuteness and number of their cells; so they still farther excel them in the astonishing abundance of their blood-vessels. The simple appearance of the organs, without any anatomical preparation, is sufficient to shew this fact; and microscopical examination, after successful injection, fully confirms it. For, although the lungs of the amphibia exhibit their dense vascular networks, beautifully painting the sides of the cells, these are not to be compared to the number and subtilty of the ramifications, eluding even the assisted eye, which every where fill up the lungs of warm-blooded animals.

Since, in the mammalia and birds, all the blood of the body must pass through the lungs, before it can return again to the organs, it was necessary to have a large number of vessels for its conveyance, and a surface for their expansion, both extensive on account of their number, and the necessity of exposing the blood in minute portions to the air, and yet confined as much as possible to one spot, that its bulk might not be inconvenient. Thus we explain that inextricable tissue of blood and air-vessels, and small vesicles or cells, which compose the lungs of mammalia and birds. All these circumstances are different in reptiles. If we may judge from the diameter of the pulmonary arteries, they receive at most a third of the circulating mass, and sometimes much less. It is not necessary that this blood should

pass back again through the lungs to return to the body; it may proceed by another route, as we have explained in the account of the circulating organs; because it does not require to be so frequently submitted to the action of the air, as in the two classes mentioned above. Hence have resulted the two great differences already pointed out between the lungs of the warm-blooded classes and of reptiles; differences which are obviously related to each other, the numerous vascular ramifications requiring numerous cells and viscera.

The pulmonary serve also as bronchial vessels in reptiles; at least we find no arteries or veins of the latter description. The arterial and venous bloods are mixed in the heart; and the sacæ that goes to the lungs is conveyed to all other parts of the body for their supply.

Yet the pulmonary are not the only arteries conveying blood to the lungs in reptiles: the serpents, at least, offer an exception. The ramifications of the pulmonary artery are confined to that part of the lung, which has a reticulated internal surface. The posterior part of the organ, composing the simple membranous bag, receives blood only from the arteries of the body. A part of the twigs that supply it comes from the branches of the posterior aorta, which are also distributed on the stomach. Other very minute ones are detached successively from the vertebral column. The veins corresponding to these arteries pour their blood into the vena cava. In this singular structure, we find a part of the lung executing the office of the cells of birds: and a portion of the blood, very small indeed, contained in the arteries of the body, is again submitted to the action of the air.

That portion of the general serous membrane which covers the lung has nothing peculiar in reptiles.

The form and bulk of the organs vary much more in this class, than in the mammalia and birds. Both are determined in the mammalia by the cavity of the thorax; in birds, by the peritoneal cells, which limit them on one side, and by the ribs, which cover them on the other. In reptiles, on the contrary, nothing seems to limit their development, nor to give them a peculiar figure. Commonly they form oval bags, which extend in the chelonians along the back to the pelvis, above all the viscera; they are less extensive in the saurians and batracians. The serpents have a single very long lung, prolonged over the œsophagus, stomach, and liver, beyond the latter parts. In this situation it is exposed to pressure every time the animal swallows a large prey. Does this check the pulmonary circulation, and contribute to the torpor which serpents experience at these times?

In the *cameleon*, and the *agame marmorata*, each pulmonary sac is very extensive. They are divided into large conical appendices, prolonged as far as the pelvis, placed among the viscera, and capable of holding so much air, as to increase the animals' bulk considerably when they are distended. The lungs of the *fren lacertina* are two long cylindrical sacs, continued to the end of the abdominal cavity. In the larvæ of the salamander, there is a small oval cavity, opening by a narrow canal in the fauces.

Branchiæ or Gills.—The first orders of reptiles (the chelonians, saurians, and ophidians) never possess this kind of respiratory organ: they have only lungs. The batracians in their first state, and the proteus and *fren* during life, have both lungs and branchiæ, or rather branchial appendages (appendices fimbriati). See the anatomy of the tadpole, and that of the proteus and *fren*, at the end of this article.

Expansive Power of the Lungs.—"A singular power," says Blumenbach, "characterises these viscera in reptiles, and

REPTILES.

is a point, in which they exceed those of the human subject, and of the other mammalia; namely, a particular kind of tone, or energy, by virtue of which, even when the chest is opened, and they are exposed to the external air, they are still distended and support themselves, while those of the mammalia, when the sternum is removed, and the thoracic cavities exposed, allow the air to rush out, and collapse. (See Morgagni *Adversar.* Anat. 5, 29, and the elegant experiments on the tortoise by the Parisian academicians; *Hist. des Animaux*, part ii. p. 194.) It is even asserted, that when the lung is compressed in a tortoise opened alive, it has the power of distending itself again. (Coiter *Obs.* Anat. Chir. p. 127.) A tortoise, from whom the lower shell had been removed, the thorax consequently being opened, and the lungs exposed to the air, survived for seven days. (*Hist. des Animaux*, just quoted.) The cause of these phenomena can only be found in the peculiar vital properties of the lungs; as it cannot be referred to contractility, irritability, or nervous influence. I have never been able to detect, in the lungs of amphibia, any more appearance of truly muscular texture, than in those of the mammalia, to which a modern author has too liberally assigned irritability. (Varnier in *Hist. de la Soc. de Médecine*, 1779.) The design of this peculiar vitality in the lungs of amphibia will appear very obvious, when we consider that it exists in animals who have a very imperfect bony thorax, or none at all, or one in great measure incapable of motion. Such is the case with frogs and toads, who are entirely destitute of ribs; with nearly all the tortoises and turtles (excepting, perhaps, a few of the soft species), in whom the whole coverings of the trunk are immovable, so that neither the thorax, nor the abdominal muscles, can execute those motions in respiration, which they perform in warm-blooded animals."

Mechanism of Respiration.—In this, as well as in other points, the several orders of reptiles differ from each other. The chelonians, whose ribs are in the form of large osseous plates, consolidated to each other, and motionless, are, in effect, like the batracians, some of which have no ribs at all, while in others these bones are too short, and too little susceptible of motion, to be capable of assisting in the process of respiration. In all these animals, then, we can no longer regard these bones as the principal agents of the respiratory function. They also want the diaphragm, like all other reptiles. Consequently the mechanism of respiration differs in them, in its essential points, from that described in the article LUNGS, which belongs to the whole class of mammalia, where the respiratory organs, inclosed in a peculiar cavity, follow all the motions of that cavity.

In fact, it is now well ascertained, that the batracian reptiles swallow air into their lungs. They close the mouth, and dilate the throat, when the external air, rushing through the nostrils, fills the empty space. The sterno-hyoidei, carrying the os hyoides downwards and backwards, are the great agents in this dilatation of the throat: the coraco-hyoidei assist them. When the former muscles are cut, respiration ceases. The elevation of the os hyoides, principally by the stylo-hyoidei, contracts the cavity of the throat, and drives the air into the lungs. The escape of this air from the throat by the nose is, no doubt, says Cuvier, prevented by a valve; but no such structure has been demonstrated. The action of the abdominal muscles, and perhaps a contractile power of the lungs themselves, expel the air from these viscera in expiration. Townson, who has investigated this subject most attentively (see his *Observationes Physiologicae de Respiratione Amphibiorum*, 8vo. Vienna, 1798, with figures; also translated into English in his "Tracts,") observes, that

he does not know whether the muscles extending from the glottis to the pubes should be called oblique or not. They surround the lungs in their whole extent, and have a considerable compressive force. They probably consist of different muscles; their fibres extend more or less transversely, and are therefore well calculated to produce the effect he has assigned to them. He states that he has always seen the frog's lungs collapse when the glottis was opened, whether the animal was dead or alive.

If the muscles and the membrane of the throat are removed, leaving only the sterno-hyoidei, the motions of the os hyoides, which take place in respiration, are continued, although respiration itself is destroyed. The latter effect is a consequence of the destruction of the throat; no cavity can now be formed to receive the air, which the animal swallows in breathing. The os hyoides, however, is alternately depressed and elevated, and the glottis continues to open and shut, but the lungs are permanently collapsed. If all the muscles employed in moving the os hyoides are cut, the glottis, whose muscles are entire, is opened and closed. In the same way, when warm-blooded animals have received a large wound in the chest, they make vain efforts to breathe, and to get rid of the painful sensation of suffocation.

It will appear, from the preceding description, that the frog's mouth must be shut when he breathes: and this is so strictly necessary, that the animal perishes from suffocation, if his mouth be kept open. Herholdt and Rafn asserted this in a communication to the Academy of Sciences at Copenhagen, and the point has been verified by Cuvier and Duméril. See *Bulletin de la Société Philomatique*, N^o 30, an. 7. p. 43.

The same mechanism is employed in the chelonians. Deglutition is the only means they can employ for introducing air into their lungs. Having the mouth closed, they alternately contract and dilate the throat, like the batracians, and by the same powers. The air is expelled from the lungs by two pairs of muscles, analogous to the abdominal muscles. These fill the posterior interval between the sternum and the back shell, in which the posterior extremities are folded when at rest. We perceive, at this part, in the chelonians, those motions of contraction and dilatation, which are observed over the whole abdomen in the mammalia.

The first, or outer pair, correspond to the external oblique muscles: it is attached to the whole anterior edge of the pelvis, to the back and front shell, and is extended in the whole posterior interval of these parts. The internal muscle consists of transverse fibres, attached above to the posterior half of the back shell, near the vertebræ, descending on the outside of the viscera, inclosing them, and terminating below in a middle aponeurosis. The latter passes partly under the bladder, and will serve to evacuate that organ when the muscles contract. They compress immediately only a small portion of the lungs; but they press strongly on the abdominal viscera, and through the latter on the lungs, so as to expel the air. Perhaps, too, the lungs may contract by some powers of their own.

The mechanism of respiration, in the saurians and ophidians, is very analogous to that of birds, inasmuch as this function is particularly executed by the motions of the ribs and of the abdominal muscles. In most of the saurians, the ribs are perfectly similar to those of birds, consisting of two portions, united by a moveable articulation, and forming an angle, which is opened in inspiration, and closed in expiration. The muscles which put them in motion are analogous to those employed for the same purpose in birds.

The ribs of serpents, forming simple arcs, composed merely

REPTILES.

merely of an osseous portion, are inclined backwards, and brought near the vertebral column in expiration, and are extended in inspiration. Elevators of the ribs, similar to those of man, but larger in proportion, produce the latter effect, in which they are assisted by intercostal muscles. The muscles carrying the ribs backwards, and thus producing expiration, lie within the chest. They are fixed to the sides of the vertebral column, and correspond in number with the ribs. They are narrow and flattened, forming a kind of muscular ribbons, passing from the vertebral column, over one rib, to be fixed in the next. Other muscular ribbons are attached to the inside of the ribs, descend to be joined together, and then extend across, ending in a thin aponeurosis, which unites the ribbons of each side. These compose the abdominal muscles, and compress the viscera of the great cavity.

Respiration, which consists in warm-blooded animals of a constant regular succession of alternate inspirations and expirations, hardly admitting even a very short interruption, is performed in reptiles at irregular and long intervals, admitting of very long suspension, and capable, therefore, in a much greater degree than in the former classes, of modification by the will of the animal. Hence Linnæus assigned a "pulmo arbitrarius," or voluntary power over the respiratory function, as a distinguishing attribute of the class. The difference, however, between the reptiles and warm-blooded animals is in the length of time for which they can do without respiration: after a longer or shorter interval, its renewal is equally necessary to both.

All reptiles continue breathing constantly as long as they are awake; and the turtles most frequently of all. It is well known that they cannot remain long under water; but are obliged, at short intervals, to come to the surface for a fresh supply of air. Blumenbach observed water newts, when placed in a deep vessel of water, swim up to the top frequently for the purpose of drawing breath.

"On the whole, however," continues Blumenbach, "reptiles cannot only go much longer without breathing than warm-blooded animals, but they can also continue unhurt in vitiated air for a much more considerable time."

"Tortoises have been known to live more than a month with their jaws tightly tied, and their nostrils closed with sealing-wax, (Mery, in Mem. de l'Acad. des Sciences, avant 1699, v. 2.) On the same point we may mention the puzzling, but sufficiently authenticated instances, of toads found alive in the middle of solid trunks of trees, and even in masses of marble and other stones. (See Luidius in Lithophylac. Britann. p. 112. Le Cat in Allion du Lac, Melanges d'Histoire Naturelle, v. 3, p. 95. Gentleman's Magazine, v. 26, 1756, p. 74. Guettard in Mem. sur differ. part. des Sciences et Arts, v. 4, p. 615. Hist. de l'Acad. des Sciences de Berlin, 1782.) There are numerous citations in Haller, de Corp. Hum. Fabrica et Functione, v. 7, p. 151, and Kaestner, in the Preface to the German version of the Stockholm Transactions, v. 3.

"Reptiles can also bear to breathe fixed and phlogisticated air much longer than warm-blooded animals. In my experiments at the celebrated cavern of Pyrmont, I constantly found that pigeons could hardly be restored to life if their immersion in that bath of carbonic acid gas was protracted into the second minute. Frogs, however, recovered after staying in it five, six, seven, and even nine minutes. The event of similar trials, made in the famous grotto del Cane, near Naples, corresponds to these. (See Nollet, in the Mem. de l'Acad. des Sciences de Paris, 1750, p. 72. Murray, in the Swedish Transactions, 1775, v. 36, p. 249.) Della Torre found that a toad lived for half an hour in that grotto,

and that a newt was still alive, after having been immersed in this pernicious atmosphere an hour and a quarter.

"Carminati has already shewn how much sooner confined air proves fatal to warm-blooded animals, than to the amphibia. (De animalium ex mephitibus et noxiis halitibus interitu, p. 96.) When I have enclosed two sparrows under one bell-glass, and two frogs under another of the same size, the former have perished in convulsions from the vitiated state of their air, while the atmosphere of the other glass had experienced so little change, that a candle or burning coals were not extinguished by it." Specimen, p. 1.

The experiments of Boyle (Philos. Transf. 1670, N° 62.), and the Florentine academicians, which have been since most frequently repeated, have shewn that serpents, frogs, &c. can remain very long (from two or three to ten or twelve hours) under an exhausted receiver.

The nature of the changes produced in the air by the respiration of reptiles, has been examined by Spallanzani (Rapports de l'air avec les etres organises, publies par Senebier, 3 tom. 8vo. Geneve, 1807); Mr. Ellis (Inquiry into the Changes produced on Atmospheric Air, &c. 1807, and Further Inquiry, &c. 1811,) and others. The latter author presents us with a summary of all that has been ascertained, as well as with experiments of his own; we, therefore, extract them in his own words from the works just quoted.

"To obtain a knowledge of the specific changes which the air suffers by the respiration of the amphibia, the following experiments were instituted. A toad, supported on a small hoop, was inclosed in one hundred and eight cubic inches of atmospheric air contained in a jar inverted over water, and standing in a room varying from 55° to 60° Fahrenheit. He died on the fifth day. The water had risen considerably in the jar, and the residual air was still farther diminished by agitation with lime-water, which it rendered turbid. Fifty parts, after being washed in lime-water, were next shaken in the eudiometer with the liquid sulphuret of potassa, and lost only one part of its bulk. The experiment was repeated by confining another toad, in the same manner, in another jar containing forty cubic inches of atmospheric air, inverted over mercury. Under the hoop which supported the animal, was placed a small cup, containing 1.5 cubic inch of the water of potassa, which floated on the mercury. The whole was then set aside in a room, of the temperature of 64°. By the twelfth hour, the mercury had risen nearly half an inch into the jar, which was thickly moistened with vapour, and the breathing of the animal seemed rather languid: by the twenty-first hour, he breathed very faintly; and, by the twenty-fourth hour, he had ceased to breathe. The jar was allowed to stand some hours, at the end of which time the mercury stood about eight-tenths of an inch high, and one-tenth of an inch of fluid was deposited on its surface. The jar was now raised, and diluted sulphuric acid being poured into the alkaline solution, excited in it a very brisk effervescence. It is inferred, therefore, from these experiments, that the oxygenous portion of the air almost entirely disappears during the respiration of these animals, after which they cease to breathe; and that a large portion of carbonic acid is at the same period produced.

"Proceeding on the supposition, that the loss in the bulk of air, evinced by the ascent of the mercury, in the last of the foregoing experiments, arose from the attraction of the carbonic acid by the alkaline solution, we endeavoured to ascertain the proportion which this loss of bulk bore to that of the whole air originally employed. With this view a frog was procured, and placed in a jar of the capacity of forty cubic inches. Under the hoop which supported

REPTILES.

ported him, about half way up the jar, was placed a small cup, containing one cubic inch of the water of potassa; and the jar being then filled with atmospheric air, was inverted into a dish of mercury, and kept steady by a weight pressing upon it. In the room in which the animal was placed, the barometer stood at 29.2 inches, and the thermometer at 61°. At the end of twenty-nine hours, the animal was resting quietly on the hoop, with no appearance of distress, and the mercury in the jar, when that in the dish was brought to a level with it, had risen six-tenths of an inch. In twenty-four hours more, the frog was still alive: his respiration seemed now to labour, and he rose often to the top of the jar, as if desirous of escaping, or of obtaining fresh air: the mercury had now risen to 1.15 of an inch. From this time, the difficulty of breathing continued to increase, and, at the close of the fifty-ninth hour, from the commencement of the experiment, after having lain quiet for a considerable time, he gave a convulsive struggle, and moved no more. The mercury in the dish was now brought to a level with that in the jar, and its height was 1.2 of an inch. The barometer, at this period, was 29.8, and the thermometer 65°.

“In order to examine the residual air, we plunged the dish under water, which rising into the jar, displaced the mercury, and the cup, with its solution, was then withdrawn under water. The residual air suffered no diminution by being shaken with lime-water, nor by contact with phosphorus, but it lost rather more than $\frac{1}{100}$ by agitation with the liquid sulphuret of potassa. The jar originally held forty cubic inches, but the animal, with the hoop, cup, and solution, occupied a share equal to four, so that the actual bulk of air employed was 36 cubic inches. Having placed the jar on its bottom, water, to the quantity of 27 cubic inches, was poured in till it reached the point to which the mercury, during the experiment, had risen; and this, therefore, indicated the volume of residual air: it then required nine cubic inches more of water to fill the jar completely, which, consequently, was the bulk of air that had disappeared. Hence,

therefore, we have $\frac{27 \times 29.8}{29.2} = 27.5547$, but $\frac{4 \times 27.554}{483} = 22819$ and $27.554 - .22819 = 27.32651$, the corrected volume of air at the close of the experiment.

But farther, $36 - 27.32651 = 8.67349$, and $\frac{8.67349}{36} = \frac{1}{4.15}$, so that the diminution of bulk which the air suffered

in this experiment is rather greater than $\frac{1}{4.54}$, the proportion of oxygen gas which the atmosphere contains. In a second experiment, another frog lived in the same volume of air about 60 hours, and the diminution which it suffered, after making the necessary reductions, amounted to $\frac{1}{4.868}$

of the whole. Where the carbonic acid, formed by the respiration of another frog, was suffered to remain, the jar, after the death of the animal, adhered firmly to the saucer in which it was inverted, and, when cautiously elevated, the surrounding mercury rushed in; and occupied only about one-tenth of the space which it filled in the above-mentioned cases: the inferences deducible from these facts, instruct us, that the diminution which atmospheric air suffers by the respiration of these animals, bears a near proportion to the oxygen gas which it contains, when all the carbonic acid is removed: and as a small loss of bulk likewise takes place

when this acid is allowed to remain, we must ascribe a part of the observed diminution to the necessary loss which always accompanies the conversion of oxygen gas into carbonic acid.

“It follows from the preceding series of experiments, that the oxygenous portion of the air is changed by the respiration of amphibious animals in the same manner as by that of the other classes, carbonic acid, in proportion thereto, being, in all cases, produced; and that when the whole, or nearly the whole, of that gas is so changed, the animal no longer survives. But, if the animal die when all the oxygen gas is changed, and all the air that has disappeared when the carbonic acid is removed, be oxygen gas, then the bulk of air that remains, and is unchanged, must consist wholly of nitrogen gas; and as this nitrogen gas, joined with the oxygen gas that has disappeared, makes up the whole bulk of air originally employed, it follows also, that, while the oxygen gas of the air has diminished and suffered change, the nitrogenous portion has continued undiminished and unaltered.

“During all these changes operated on the air contained in water, by the respiratory functions of aquatic animals, the water itself seems to suffer little or no alteration. Mr. Carlisle took separate glasses, each containing one pound of distilled water, which was previously boiled to expel all its air, and then inverting them over mercury, he put into them one gold fish, one frog, two leeches, and one fresh-water muscle. The animals were confined several days in these situations, and exposed to the sun during January, in temperature 43° and 48° Fahrenheit; but no air-bubbles were produced in the vessels, nor was there any sensible diminution of the water. The frog died on the third day, the fish on the fifth, the leeches on the eighth, and the muscle on the thirteenth day. This experiment was made to ascertain the changes produced in water by the respiration of aquatic animals; but the water had not undergone any chemical alteration. See Croonian Lecture in the Philof. Transf. 1805.” Inquiry, p. 83—88.

Mr. Ellis adduces some additional evidence in his Further Inquiry. “The experiments already detailed in the former work clearly prove, that frogs and toads which belong to this class, entirely convert, by respiration, the oxygen gas of the air into nearly an equal bulk of carbonic acid, without producing any change in its nitrogenous portion. Dr. Carradori also discovered, that these animals lived much longer when they were immersed in water that had a free communication with the atmosphere, than when the air was excluded. (Phil. Mag. vol. 16. p. 245). According to Spallanzani, frogs die sooner in boiled, than in common water. In their respiration, they consume oxygen, and form carbonic acid. Those which have been recently fed, consume more of this gas than those which have suffered a long abstinence. Under great cold they become lethargic, but their heart still continues to beat, and they still, in a smaller degree, continue to change the air; but the consumption of oxygen increases with the increase of temperature. These animals also change the air by their skin, as well as by their lungs; and act upon it after death, and under putrefaction. (Rapports, &c. tom. i. p. 468.) The ova of frogs were likewise found to require air to carry on their evolution. Small tadpoles, while yet attached to the egg, were confined in vessels half filled with water, while the other half contained air, or oxygen or nitrogen gas. Those in the two former vessels were perfectly developed, and became large enough to swim about; but those confined with nitrogen perished. Rapports, &c. tom. i. p. 466.

“Spallanzani extended his experiments to many other animals

REPTILES.

mals of this class, and obtained similar results. Different species of serpents he found to die in hydrogen gas, or when confined under water, but to live in common air, and convert its oxygenous portion into carbonic acid. They became lethargic from cold, and the heart then beat very slowly, or not at all, the respiration was then also suspended, and little or no effect was produced in the air. The skin of these animals acted upon the air, as well as the lungs (Rapports, &c. tom. i. p. 249.); and when the blood was reddened by exposure to the air, its oxygen also disappeared, and carbonic acid was produced. (Rapports, &c. tom. i. p. 239. 263.) Similar results were obtained in experiments on the respiration of vipers, tortoises, lizards, and salamanders. Rapports, &c. tom. i. p. 275. 287. 295. 353.

“The preceding facts sufficiently shew, that various animals in all the foregoing classes, and in every stage and form of their existence, require the presence of oxygen gas to maintain the functions of life; that this gas, by the exercise of these functions, is converted into carbonic acid; and that the degree in which this conversion proceeds, depends much on the healthy condition of the animal, and the vigour of its circulating system. Since, also, in every instance where the experiments have been made with the requisite accuracy, the bulk of carbonic acid produced, nearly or exactly equalled that of the oxygen which disappeared, we may conclude, from analogy, that such is universally the extent to which this change in the air takes place in animal respiration; and since, farther, the nitrogen gas of the air appears to suffer no necessary change in the exercise of this function, we may also conclude, that as far as regards the air, the substitution of an equal bulk of carbonic acid for the oxygen gas that is lost, comprises the only essential change which the atmosphere experiences during the performance of this animal process.” P. 269—272.

Vital Temperature.—“Since the respiratory organs,” says Blumenbach, “may, with great probability, from the numerous investigations and discoveries of the moderns, be regarded as the principal source of animal temperature, we follow a natural arrangement in passing from the consideration of their structure and functions, to a short view of the differences between the natural heat of reptiles and warm-blooded animals.

“Animals, whose lungs are most compact, receiving the greatest supply of blood, and furnished with all the apparatus necessary for sending the whole circulating mass through the minor circulation, are obliged to keep up the respiratory process uninterruptedly from the time of birth, expelling, instead of the pure aerial fluid which they inspire, a noxious air, which corrupts the surrounding atmosphere if confined, possess a high natural temperature, about the 98th degree of Fahrenheit’s scale in man, rather higher in some mammalia, and particularly in birds. In reptiles, on the contrary, possessing lungs of a rare and loose texture, with comparatively slender supply of blood, respiration is irregular, interrupted, and in some measure arbitrary; they very slowly vitiate confined air; and exhibit a temperature exceeding, by a few degrees only, that of the surrounding atmosphere. One or two degrees, I say, according to the results of accurate observation on tortoises (Walbaum Chelonograph. p. 26.): for my own experiments on amphibia have not exhibited results sufficiently constant to allow me to draw any certain inference from them.” (Specimen, &c. p. 18.) Braun, indeed, has asserted, in the Nov. Comment. Acad. Petrop. t. 13. p. 427, that frogs possess only the temperature of the surrounding medium; but the facts which

we shall advance presently, completely disprove this assertion.

The power which modern investigations have proved warm-blooded animals, and more particularly the human subject, to possess in so high a degree, of being able to endure exposure to heat much above the natural temperature of the body, without having their own heat increased; and, on the contrary, of bearing, with equal facility, the most intense cold, is not withheld from the amphibia, as is proved by the facts which we have related, in order to shew the tenacity of life in this class. It is not, indeed, clear in these cases, as in the experiments, of which man and different mammalia have been the subjects, that the reptiles, when exposed to a degree of heat greater or less than their own, have maintained their own temperature at an uniform standard; on the contrary, indeed, it seems that in a great cold their heat is abstracted, and they become frozen; and it will also be seen, from facts to be brought forward presently, that their heat is variously changed under different circumstances. Now we know that the temperature of the mammalia is not raised beyond its natural level by exposure in an atmospheric medium of 280° Fahr. (see Tillet in Mém. de l’Acad. des Sciences, 1764); and that its standard is equally undisturbed, when the atmosphere is below the freezing point of mercury. (See HEAT, *Animal*, and *MAN*.) We may therefore safely assert that man and the mammalia very far exceed reptiles in the power of resisting either great heat or cold; that is, of maintaining a standard temperature under the action of a surrounding atmosphere, considerably exceeding or falling short of their own temperature. The following summary of facts, concerning the temperature of reptiles, is taken from Mr. Ellis’s Inquiry.

“Amphibious animals exhibit a great variety in the structure of the respiratory organs, and, consequently, in the degrees of animal heat. Frogs and land tortoises possess a temperature about five degrees higher than that of the medium they inhabit, according to Dr. Martine. The same may be said of sea tortoises, toads, vipers, and all the serpent kind, all of whom have lungs of the same fabric and the same cold constitution of body. (Essay on Thermometers, p. 142.) Mr. Hunter observed that the frog and toad were about four or five degrees warmer than the atmosphere when it was at 35° or 36°; and that, some hours after death, they gradually fell down to the temperature of the surrounding air. (Treatise on the Blood, p. 298.) The difference of temperature appears to increase in a warmer atmosphere; for Mr. Carlisle kept three frogs for many days in an equable atmosphere of 54°, and their stomachs preserved a temperature of 62°. (Philos. Transact. 1805, pt. 1.) In an atmosphere of 58°, Mr. Hunter found the thermometer, introduced into the stomach of a healthy viper, to stand at 68°; but, after the animal was put into a pan, and the pan into a cold mixture of 10°, where it remained about ten minutes, the heat was reduced to 37°, and, in twenty minutes more, to 31°, nor did it sink lower; its tail now began to freeze, and the animal was very weak. A frog also, whose temperature was 44°, when put into a cold mixture, soon fell down to 31°; and beyond this point it was not possible to lessen the heat without destroying the animal. (Obs. on the Animal Economy, p. 104.) A toad being placed in cold water, just deep enough not to cover his mouth, the whole was put into a cold mixture between 10° and 15°. The water froze around the toad, and, as it were, closed him in, but he did not die, and therefore was not frozen. Why the animals, mentioned in these experiments, died before they were frozen, while those which are

REPTILES.

exposed to the atmosphere, in very cold climates, do not die, is a point which Mr. Hunter does not pretend to determine; not knowing the difference, he says, between the effects of a natural and artificial cold. Ibid. p. 89, 90.

"The experiments of Mr. Hunter farther prove that the temperature of most of the foregoing animals not only falls rapidly in a colder medium, but that it rises more quickly in a warmer one than that of those which possess a higher standard temperature. In the stomach of a frog, the thermometer rose from 45° to 49° ; the animal was then placed in an atmosphere made warm by heated water, where it remained for 20 minutes, and upon introducing the thermometer again into the stomach, the mercury rose to 64° . (Ibid. p. 90.) A healthy viper was put into an atmosphere of 108° , and, in seven minutes, the heat of the animal, both in the stomach and anus, was found to be 92.5 , beyond which it could not be raised in the above heat. An eel, very weak, whose heat was 44° , which was nearly that of the atmosphere, was put into water heated to 65° , for fifteen minutes; and, upon examination, it was of the same degree of heat with the water. The heat of a tench was, in ten minutes, raised from 41° to 55° , both in the stomach and rectum, by being put into water at 65° .

"He found also, that a living and dead tench, and a living and dead eel, put together into warm water, received heat equally fast; and when they were exposed to cold, both the living and the dead admitted the cold likewise with equal quickness. (Ibid. 104, 105.) Hence, therefore, the animal heat, in all the classes of animals hitherto mentioned, whether they inhabit the air or the water, seems to follow nearly that of the medium in which they are placed; and their standard temperature cannot, in consequence, be restricted to any fixed point, but must be considered always in relation to that of their surrounding medium.

"Notwithstanding, however, the low degree of heat which these several classes of animals possess, hardly, in some instances, exceeding that of the medium in which they live, yet this small excess is a proof that they possess, within themselves, a power of producing heat. The loss of heat which insects suffer under cold, the fall of temperature which many of the vermes class undergo from the same cause, the melting of snow by the heat of fishes, and the decline of animal heat which the amphibia, when exposed to great cold, experience, all demonstrate that the surrounding medium, whether it be air or water, is constantly drawing off their heat, which renders necessary as constant a re-production of it." P. 218—221.

The great size and beautiful structure of the lungs of reptiles lead us to conclude that they are very important organs in the economy of these animals, although their uses and relations are not yet all satisfactorily ascertained. It seems tolerably certain, that besides their office as respiratory organs, they render the body lighter for swimming in many instances: in this point of view they may be compared to the swimming bladder of fish. It is by the inflation of its large lungs, that theameleon can distend its body so remarkably.

"The lungs, too," says Blumenbach, "are subservient in many reptiles to the production of sound;—I say in many, because some species, even of our reptiles, are, so far as I know, completely dumb: viz. the salamander, *lacerta agilis* (green lizard), and *anguis fragilis* (blind-worm); and others utter sound very rarely, and only when in great danger, as the water newts; resembling, in that respect, the mole and hare, which do not cry out until great violence is offered them.

"It has been reported that some mammalia lose their voice

in particular situations, as dogs in certain parts of America; the same thing has been reported of reptiles, for example frogs, which G. F. Müller found to be dumb in many regions of Asiatic Russia. Sammlung Russischer Geschichteten, vii. p. 123." Blumenbach, Specimen, &c. p. 15.

Organs of Voice.—The larynx, varying in different genera, as in the other classes, has these characters in common; viz. that it has no epiglottis, and is composed of pieces analogous to those of the upper larynx of birds. This is the only vocal organ; there is never an inferior larynx, as in birds. The voice cannot be modified by lips or velum palati, since they do not exist. The degree of aperture of the mouth, and the motions of the tongue, are alone capable of modifying the action of the larynx.

The cartilaginous skeleton of the crocodile's larynx contains five pieces: a nearly square plate, composing all the under surface of the cavity. Two circular pieces or handles, fixed near together at one end, in the middle of the front edge of the plate, and at the other, in the middle of the side. Their body is a little elevated above the square plate, and leaves on each side, between it and that plate, a membranous hollow. The anterior extremity of each piece forms a lateral and vertical prominence, constituting a kind of pillar under the glottis. To the posterior external angle of this plate, a branch is fixed on each side; these join together above, and form, with the back edge of the plate, a complete ring, which is the beginning of the trachea.

The glottis is merely membranous, extending from the junction of the two last-mentioned branches to the middle of the os hyoides, where the membranes composing it are attached. There are neither ventricles nor chordæ vocales. Two muscles act on this apparatus. One comes from below the great plate, surrounds the larynx, ascending obliquely backwards, and joins the corresponding muscle of the other side behind the glottis, which it has the power of closing. The other comes from below the back edge of the same plate; decussates the former, ascending obliquely forwards, and is fixed to the edge of the glottis, which it opens. The first half of the glottis corresponds then to the broad and flat cavity of the larynx; the second, beginning from the two pillars in front, is merely a long and narrow slit. It is only in striking against the two pillars, that the air can produce a whistling noise, if indeed any such be produced at all.

The glottis of the crocodile of the Orinoco, says Humboldt, is surrounded by a thick fleshy ring with circular fibres, which the animal can contract to such a degree, that the slit or opening of the trachea cannot be distinguished. The glottis rests on a round and flat cartilage, analogous to the thyroid of mammalia. The upper part of the trachea presents a singular structure, which we mention here, because it seems subservient to the production of sound. The first nine cartilages are not complete rings, but are joined together above by a transparent, very fine and tense membrane. (See Humboldt Recueil d'Observations de Zoologie et d'Anatomie comparée, t. 1. pag. 11. pl. 4.) Geoffroy observed ten annuli thus united in the Nilotic crocodile; Duvernoy sixteen, in a crocodile dissected at the Academy of Sciences, and the Jesuit Missionaries in Siam a larger number. To this membrane, stretched like the parchment of a drum, and thrown into vibrations by the air, the deep and terrific howlings or bellowings of these dangerous reptiles are ascribed; the glottis being at the same time closed by its muscular ring. Annales du Muséum, t. 2. p. 46.

In the iguana, the pillars are scarcely more prominent within than the rest of the parietes; the glottis is very short,

REPTILES.

short, and the inferior plate goes forwards and becomes broader, being turned up to form the rudiment of an epiglottis.

The same simplicity of structure prevails in the tupinambis, the common lizard, the tortoises, and serpents; an inferior plate, and two lateral pieces narrowing a little the edges of the glottis. These animals can only be capable of producing hissing sounds.

The mud tortoise has, at the bottom of its organ, a rounded depression, which is not so well marked in the turtle; but it has not any vocal chords. In a great land tortoise of Madagascar, there is a triangular membranous crista, attached to the lower part of the larynx, and ascending in the glottis, which it divides into two. This is analogous to a structure very common in the upper larynx of birds. The edges of the glottis are flat, sharp on the outside, and touch completely.

In the scink, the edge of the glottis is turned a little inwards to form a tense membrane, directed backwards.

In the cameleon there are pillars, nearly as in the crocodile, but they are each furnished with a tense membrane directed backwards, and very fit for vibration. In front of them, on each side, a fleshy protuberance is observed, contracting the glottis, which is very short, and terminating in front by a transverse slit. But the most remarkable circumstance about the larynx of the cameleon, is a small membranous sac opening below, between the inferior plate of the larynx, and the first ring of the trachea.

Neither the iguanas nor the dragons possess a similar sac, although we observe in them goitres on the outside: these prominences have no relation to the vocal organs.

The frogs, which are so noisy, have a larynx suitable to this character in the size and prominence of its vocal chords. The inferior plate of the larynx is a slender transverse branch, bearing on each side a large ring, which is the origin of the bronchus; for, in these animals there is no tracheal tube. On the front of the transverse branch, two oval pieces are articulated, convex externally, and concave internally, so as to resemble kettle-drums. On the lower edge of each a membrane is stretched internally, which opposes at right angles the course of the air. The edge of this membrane forms the chorda vocalis, which is consequently more isolated than the cartilages, and freer than in any other animal. Above it is the opening of the ventricle of the glottis, occupying all the concavity of the kettledrum cartilage. The upper edge of this cartilage forms the margin of the glottis properly so called. Vicq' d'Azyr conceived that the ventricles communicate by their bottom with the bronchi, and thus ascribed three openings to the larynx of frogs: but this is a mistake.

Besides this apparatus, which is extremely sonorous, male frogs have two bags, each of which opens by a small hole, not in the larynx, but in the bottom of the mouth, at its sides. They pass under the arch of the lower jaw, to make a prominence under the skin on each side under the ear. These bags are distended when the frogs are croaking. They are covered by a muscular tissue capable of compressing them. The female frogs, and toads of both sexes, and the tree-frogs, are destitute of the bags; but the latter have a simple sac under the throat. In this larynx there is a muscle on each side to separate the oval cartilages; and a transverse one in front, passing between them, and calculated to approximate them. For representations of these laryngeal sacs in the frog, see the German collection of Camper's smaller writings, vol. 1. pt. 1. pag. 144. tab. 3. fig. 1—4. Vicq' d'Azyr has represented the rima glottidis of the tortoise, frog, and serpents, in the Memoires de l'Acad. des Sciences.

1779, tab. 13; and Tyfon that of the rattlesnake, in the Philos. Transf. vol. 13. The chordæ vocales, too, are larger in the male than in the female frog.

Voice of Reptiles.—The tortoises and turtles are said to have the power of producing a more or less strong hissing, when affected by any lively feeling; but we do not know of any very clear and satisfactory testimony on the subject. Pliny's observation about the snoring of turtles when floating asleep on the water, has not been confirmed. The large iguanas utter sharp whistling or hissing sounds as they run about the tops of trees. Several serpents hiss, and the large species very loudly. The noise made by the tail of the rattlesnake is not a vocal sound, but produced by a peculiar organ, which we shall describe.

Daudin asserts, that salamanders produce two kinds of feeble sound out of the water; the first is a low sound, produced in the throat, which they swell for that purpose; the second consists in a slight striking of the two lips together, without any motion of the throat.

According to the traveller Bartram, crocodiles produce most prodigious noises. The sound is terrific, particularly in the spring, when these dangerous animals copulate. The noise resembles distant thunder, shaking the country and making it re-echo far and wide. When they are thus bellying by hundreds and thousands at a time, we might suppose, says Bartram, that some violent shock agitates the globe, and shakes it to its very foundations. He also states, that when they strike their jaws together they make a surprising noise, like that of a heavy plank forcibly beaten against the ground.

Humboldt says that the young crocodiles make a noise like cats; and that they utter very piercing cries, just after escaping from the egg, if attacked by a dog. He never heard any vocal sound produced by the old crocodiles; although he lived among them five years, and the fire often attracted them within a few paces of the tents at night. The Indians asserted that the crocodile makes a noise like that of a cow; that its voice is very terrific, but seldom heard, and sometimes just before an earthquake, the approach of which they are said to discern. Recueil d'Obs. de Zool. et d'Anat. Comp. p. 11.

Organs of the Generative Functions.—There is a very close analogy in the structure of these parts between reptiles and birds: in both classes there is a cloaca, that is, a cavity common to the generative organs, the feces, and the urine; in both the male has testicles inclosed in the abdomen, while the female organs consist of ovaries and oviducts. The young being leaves the mother in the form of a small egg, which is generally developed out of the body. The generative process, however, in many instances, exhibits in this class very striking peculiarities.

Male Organs.—*The testicles:* the situation and structure of these glands in the three first orders are very analogous to those which they have in birds. They are constantly found in the abdominal cavity, united to the inferior surface of the kidneys (in the chelonians), in front of the latter viscera on each side of the vertebral column (in the saurians and ophiidians), or immediately under their anterior portion (in the batracians). Their form varies in the different genera; they are separated, in the salamanders, into two spherical bodies, placed one before the other.

The kidney, testis, and epididymis, lie close together in the testudines, according to Blumenbach; but each of the three organs may be distinguished by its peculiar colour and structure on the first view. There is much obscurity in the different descriptions of the male organs in the turtle and tortoise. Schneider has collected the various obser-

REPTILES.

vations on this subject in his natural history of the genus testudo.

Their substance exhibits, in the tortoises, large fasciculi, of which the divisions pass in various directions, united by cellular tissue: these fasciculi are fine, cylindrical, and easily separable in the lizards. In the crocodile, according to Geoffroy, the testes are like those of fish, narrow and elongated, and lying above and in front of the kidneys (probably more correctly in front of and below these glands). In the batracians we can distinguish merely an agglomeration of small white grains interspersed with blood-vessels. No corpus Highmori can be discerned.

Yellow appendages, consisting of a fatty substance surrounded by a membrane, and floating in the abdomen, are connected to the front end of the testes in the frogs and toads.

The *epididymis* of the chelonians is a packet made up by the convolutions of a large canal (the vas deferens), which is tortuous in its whole course, and ends in the cloaca at the part corresponding to the basis of the penis and its canal. It forms, in the lizards, a detached body, large and pyramidal, larger than the testicle, adhering to it only by a small thread, and evidently made up entirely of the convolutions of the vas deferens. The latter passes along the outer edge of the kidney to the cloaca, in which it opens.

In the crocodile the semen is conveyed into two vesiculæ of considerable size, contiguous to each other, placed at the back of the common cloaca, and partly included in a cartilaginous sac. They open into the cloaca by six or seven holes on each side, arranged in a circular form round the meatus urinarius. Geoffroy. If these are vesiculæ feminales, it is the only example we know among reptiles of such organs.

The testis is long and slender, and the relative bulk of the epididymis is less in the ophidians; it soon changes into a vas deferens, also very tortuous, opening in this, as in the preceding orders, into the cloaca. In the latter only the canals are inserted in a papilla, which has been incorrectly described as a penis. A more minute account of these organs in the viper, may be seen in Charas, Description Anatomique de la Vipère.

Vesiculæ Seminales.—There is no reservoir analogous to the vesiculæ feminales properly so called, nor to the accessory vesiculæ of some mammalia in any of the other classes of vertebral animals. They have been spoken of in the viper and the batracians, as well as in some birds; but it seems that a simple dilatation of the vas deferens has been mistaken for them. Possibly future researches may shew that the arrangement mentioned above in the crocodile constitutes an exception to this remark. This is the statement of Cuvier. Blumenbach speaks of large vesiculæ feminales in the frog, which are wanting in the toad. § 324. (See Roefel Hist. Ran. Nostr. tab. 5, 6, and 21.) Charas, in his description of the viper, speaks of two reservoirs connected with the vasa deferentia, and always full of a fluid, like that of the testicles, under the name of vesiculæ feminales.

The secretion of the testicles, as observed by Spallanzani in the frog and toad, was a transparent fluid like water. From the parts, which he calls vesiculæ feminales, of the frog, he could procure at the time of copulation from two to three grains of this fluid. In the water newt it was, in colour and consistence, like thick milk. He could not discover in it any remarkable sensible property—nothing pungent—nothing acid or alkaline. (Dissertations, v. 2.) He also found the seminal fluid, both of the frog and newt, to abound with the living vermicali. Tracts, v. 1. p. 300 and 301.

Organs of Copulation.—There are two species of union between the male and female. In the greater number there is a male organ introduced into the body of the female, and conveying the fecundating liquor: but in the batracians, which have no male organ, there is merely a conjunction of their bodies, it is a prehension by the male rather than a true copulation.

In the males of those batracians which copulate thus, there is a peculiar organization of the skin of the hand. Firm tubercles, composed of hard, blackish or brown papillæ, cover not only the thumb, but also the palm of the hand. These being pressed into the skin of the female, give the male a very firm hold. They disappear after the season of copulation, and are not seen again until that season recurs. The copulation of the frog kind is effected in the following way: the male ascends the back of the female, passes his front limbs under her axillæ, and carries them round the chest, until the fingers cross in front. He continues grasping her firmly in this way until the laying is finished. The posterior part of his body passes beyond that of the female, so that he can fecundate the eggs as they are expelled, and he is said to assist in that operation. They remain joined for several days, and the grasp of the male is so firm, that great force is necessary to separate him. Confusion and laceration of the breast, and even the death of the female, sometimes follow the violent straining of the male. (See Spallanzani's Dissertations, vol. i. p. 17.) The males are more brilliant at the season of copulation, which takes place only once a-year, in the early spring; they inflate their vocal bladder more frequently, and indulge in their croaking noise. In the salamanders a crest, with divided edge, appears on the back and tail, and is afterwards, in great measure, lost.

The duration of copulation in the frogs is inversely proportional to the warmth of the atmosphere. When this is considerable, the female will be free in five or six days; but, in a cold season, the embraces of the male continue for eight or nine days. The season of re-production is the beginning of spring: in the very first days, the frogs begin to stir themselves in our marshes and ponds: they copulate, lay and fecundate their eggs very soon. At the same season, the tortoises, lizards, and serpents, accomplish the same process. Sometimes frogs are found united even before the frosts have ended. Daudin found two frogs in copulation in the middle of February, the thermometer of Reaumur at 3° above zero; it descended in the night to 4° below 0; and the pond was frozen for two days; at the end of which time the female began to lay. Hist. Nat. des Reptiles, vol. i. p. 207, 208.

One of the toads, on which Spallanzani made his experiments, copulates in the beginning of March or end of February, before all the snow is melted; the process lasts ten, twelve, fourteen, or even twenty days, if the season be cold. Spallanzani, ch. 3.

The abdomen swells greatly in both sexes during copulation; in the female, from the enlargement of the ova; in the male, from the deposition under the skin of a very limpid water, which disappears after the laying.

The tree-frogs, at least that of Europe (*Hyla viridis*) do not copulate like the frog and toad. The male fixes himself on the female, by merely applying his anterior paws under her axillæ, and employing the tubercles of the fingers. He remains in this situation for twelve or fifteen hours, or even, according to Roefel, three days.

The salamanders do not copulate at all; the male places his head on that of the female, and discharges the seminal fluid, which is received by the female organs. See Spallanzani,

zani, Diff. vol. 2; and Latreille, Histoire Naturelle des Salamandres de France.

Penis.—The chelonians have one; most of the saurians, and the ophidians, have two; and the batracians none. There is a papilla in the cloaca, in place of the penis, but none in the toad.

The relative size of the organ is more considerable in the chelonians than in the mammalia and birds. It is long, nearly cylindrical, and expanded at the end, which terminates in an obtuse hook-like point, somewhat resembling the end of the elephant's trunk. A deep groove runs along the whole upper surface of the member, and is even deeper near the glans. It terminates on the broad expanded end of the latter, by an orifice divided into two by a papilla. The approximation of its edges converts this groove into a canal: it supplies the place of the urethra. This penis is composed of two corpora cavernosa, confounded together in a part of its extent. They begin by two vascular swellings analogous to the bulb of the urethra: their tissue is continued into two canals, of which the fibrous parietes, at first thin, soon become very thick, while their cavities diminish, and are united near the glans into one. The whole large swelling composing the glans is merely a development of the vascular tissue of the latter, covered by a loose and plaited skin, and supported by a prolongation of the fibrous side of the corpus cavernosum.

The skin of the groove is covered by a cavernous texture, analogous to that of the ostrich; and there is, on each side of this groove, a canal, the orifice of which is in the cavity of the peritoneum, on each side of the bladder, while the canal itself is prolonged in the substance of the penis, as far as the glans, where it ends in a cul-de-sac, without its sides appearing perforated in any part.

This penis has two retractor muscles, arising in the pelvis, and reaching as far as the glans. They fold back the penis in the cloaca, so that, like the penis of the ostrich, it shuts the orifice of the rectum, and that of the bladder. Erection, and the action of the sphincter, bring it out of the cavity.

The penises of the lizards and serpents are short, cylindrical, commonly beset with white, hard, and pointed papillæ, which have been tolerably well compared to the prickles of the hedge-hog. These organs, in their collapsed state, are drawn within the skin of the tail: when erect they are protruded, and appear at each angle of the external slit of the cloaca. They have two retractor muscles, arising under the first caudal vertebræ. Tyson has figured the penis of the rattlesnake and viper in the Philos. Transf. v. 13, tab. 1; and the latter is minutely described by Charas.

The penis of the crocodile is single, and lodged in a fold of the anterior part of the cloaca. It is composed of a firm cartilaginous substance, terminated by a glans of softer texture. It is excavated in its whole length by a deep groove. It has a very large retractor muscle, which is so considerable as even to cause a swelling of the tail.

In the saurian reptiles, as in the frog and salamanders, the male fixes himself on the female, and obliges her to turn towards him the posterior part of her body, and a real copulation ensues.

The act is differently accomplished in the serpents: the male and female twine round each other, are closely connected by several turns, and remain thus adherent for one or two hours. Is the small horny spur, situated on each side of the anus in the box, and retractile under the skin, employed at all by the serpent as an organ of prehension, like the cutaneous tubercles of the hand of the ranæ? The

faurians and serpents conceal themselves carefully for this purpose.

Although the chelonian reptiles seem so little calculated for copulation, this process takes place in them, the male fixing himself to the female by attaching the nails of his front limbs to the soft skin of her neck. Naturalists are still uncertain, whether turtles are joined plastron to plastron, as Lacépède has asserted in his Natural History of Oviparous Quadrupeds, or whether the male mounts on the back of the female, as Bomare has represented it in his Dictionnaire d'Histoire Naturelle. From the word *cavalage*, employed by the French mariners to denote this union, we may infer that they copulate like the frogs: the expression denotes clearly that the male is mounted on the female as the stallion is on the mare (*cavale*). Catesby, in his Natural History of Carolina, asserts that they remain united for many days.

Female Organs of Generation.—Reptiles have two ovaries, usually much more considerable than the single ovary of birds. For most of the year these bodies are small: but they acquire, at the propagating season, an extraordinary development, and thus distend the abdomen very remarkably. This is particularly observable in the frog kind.

In autumn and winter, says Spallanzani, the immature eggs lie all in the ovarium, which is divided into two lobes: these lobes consist of lesser lobes, each of which is invested with a peculiar membrane. The eggs are of two sizes; some very small, so as to be scarcely visible with the naked eye; others seven or eight times larger; both kinds are globular. The smaller are of a livid grey colour: of the larger one hemisphere is white, the other black. The slightest touch is sufficient to burst them, after which they are resolved into a cineritious viscid liquor. (Dissertations, v. 1. § 4.) The black spots of the surface, supposed by Valisneri and others to be the rudiments of the tadpole, are attached to the internal membrane, and have no connection with the eggs. In the spring the eggs of the largest kind are still larger, and they are mature when copulation takes place. In the first periods of copulation, they are found in the sac of the ovarium; during the succeeding times, partly in the ovarium and partly in the oviducts, where they become enveloped by their covering of viscid transparent mucilage.

The ovaria of the salamander contain a multitude of little eggs of a yellowish-white colour, smaller than husked millet, and not floating loose in the cavity of the ovaria, but adhering to their sides. These increase in size at the approach of spring.

The ovaria are connected to two long productions of peritoneum, which are fixed on each side of the spine down to the pelvis. The ova are ranged along the loose edge of this fold, either in a single row, as in the chelonians, or agglomerated in a much larger number, as in the batracians. Their blood-vessels extend between the laminæ of these membranous productions. In the batracians there are yellow fatty appendages to the ovaries, like those of the testicles.

In the serpents, like all their other viscera, they partake of the elongated figure of the body. The ova, consisting of yellow vesicles, resemble rows of beads.

Oviducts.—There are two in all reptiles, like their ovaries. They are membranous canals, fixed on each side of the vertebral column by a production of peritoneum. They commence by an expanded orifice (fimbriated opening of the Fallopian tube in mammalia), at which the ova enter. The tube is first conical, diminishing a little in size; then it is cylindrical in the rest of its course, which has a much greater propor-

tional length than in birds. In consequence of this length of the canal it is plaited on the production of the peritoneum in the chelonian, saurian, and ophidian orders, or extremely finuous and folded on itself in the batracians. When the curvatures are destroyed, and the duct is stretched in a straight line, it is four times the length of the animal in the salamander. Its parietes consist at first of a thin membrane, they become afterwards thicker, and assume the appearance of a glandular structure. The oviducts end in the frogs by a dilatation, which opens into the cloaca.

The thick fleshy part of the oviduct in the tortoises has been frequently called the uterus: the two oviducts open separately. Caldesi osservaz. intorno alle Tartarughe, tab. 6, fig. 9, 10.

An uterus is also spoken of by some in the frogs, although the generation of these animals has nothing in it like utero-gestation, and the ova are simply transmitted through the tubes, without being retained in them to undergo any part of their development. "The frogs of this country," says Blumenbach, "have a large uterus divided by an internal partition into two cavities, from which two long convoluted oviducts arise, and terminate by open orifices at the sides of the heart. As the ovaria lie under the liver, it is difficult to understand how the ova get into the above-mentioned openings. The uterus opens into the cloaca." (Comparative Anatomy, translated by Lawrence, p. 446.) "The toads have not the large uterus, but their oviducts terminate by a common tube in the cloaca." (Ibid.) For delineations of these parts in the frog and toad, see Roefel, tab. 6, 7, 8, and 21. The rana pipa (Surinam toad) has the same structure. See Camper in the 9th vol. of Commentat. Soc. Reg. Scient. Gotting. p. 129. Also in his Kleinere Schriften, v. 1. pt. 1. tab. 3, fig. 1.

Female Organs of Copulation.—The male penis in copulation passes into the female cloaca. Does it go into the oviducts?

The chelonian reptiles have a clitoris very analogous to the penis of the male, from which it differs only in its smaller size. It is long, grooved lengthwise, and terminated by a rounded glans. Retractor muscles, analogous to those of the penis, draw back the clitoris into the cloaca, when it has been extended.

No clitoris has been discovered in the other reptiles.

Dorsal Cells of the Rana Pipa (Surinam toad, *bufo dorsifer*).—It is singular enough to meet with in a toad a structure analogous to that of the abdominal pouch of the marsupial mammalia. The skin of the bulk is excavated in the female pipa by a large number of cells, (of which, Cuvier says, eighty have been counted,) in which the ova are placed, and changed into tadpoles, and the latter grow and are metamorphosed. As far as an examination of individuals, preserved for a long time in spirits of wine, will enable us to judge, the parietes of these cells do not seem to have any thing in their organization distinct from the rest of the skin.

Naturalists supposed at first, that the ova grew on the back of the female, and that the male fecundated them in that situation: but observation of the living animal, and anatomical investigations, have shown the incorrectness of this notion; have proved, that the generative organs resemble those of other female toads; that the pipa lays her ova like the other toads; and that the male fastened on her, as in the ordinary mode belonging to this order, covers her with the eggs after they have been fecundated. The eggs are then enveloped in a fluid, which causes the skin of the back to swell round them: thus they are contained in

rounded cavities. The tadpoles are produced there, with their membranous tails, and are developed in this situation, which they do not quit until they have reached their perfect state. The female then causes the cells to disappear from her back, by rubbing it against hard substances. Besides the works of Camper already referred to, concerning the anatomy of this extraordinary creature, see Blumenbach's *Abbildungen*, N^o 36, for excellent figures of the animal, and of its young in three states: 1st, as a long-tailed tadpole, with small processes of hind legs, and no trace of fore limbs; 2dly, as a four-footed creature, with the tail reduced to an insignificant size; and 3dly, with the tail entirely removed. The skeleton is figured by Schneider, in his *Hist. Amphib. Fascic. 1*.

Physiology of the Generative Organs.—In the whole class it is quite obvious, that the germ or rudiment of the new being is produced by the female in the ovarium, a point which does not admit of direct proof in the mammalia. This "pre-existence of the germ" to the act of copulation, and its formation in a peculiar organ of the female, demonstrated so clearly in reptiles, illustrate one of the most curious points in the theory of the natural reproduction of organized beings, or generation, and overturn many of the speculations on that subject. These germs acquire considerable size in the ovaries, and are therefore distinctly visible before the approach of the male. They pass from the parts just mentioned into the oviducts, and thence out of the body through the cloaca, having received in their passage through the ducts some external coverings. An application of the fecundating liquor secreted by the male is necessary to the evolution of these germs; they may be ejected from the body without the embraces of the male, as in the frog, toad, or newt, if they are forcibly separated from the male after copulation has begun, but then they are not evolved.

Swammerdam and Roefel were of opinion, that the eggs were loose in the abdominal cavity, and taken up thence by the oviduct. Spallanzani found them in the abdomen only thrice in more than two thousand dissections; and hence supposes that the circumstance must have been a deviation from the accustomed course in these instances.

Although the motions and vital functions of reptiles seem very languid in comparison to those of the warm-blooded classes, they exhibit considerable ardour and manifestations of lively feeling in their amours. "As soon," says Spallanzani, "as the eggs begin to be discharged, the agitation of the female is extreme; she darts backwards and forwards, rises towards the surface of the water, and then sinks, keeping the hind legs constantly stretched out, and croaking in a low voice. The male, keeping his hind legs close to his body, throws himself into strange contortions, and accompanies the croaking of the female with a kind of interrupted noise, which I cannot express by words." *Dissertations*, v. 2. § 11.

In the work just quoted, which contains the most original and interesting collection of facts concerning the whole affair of generation, Spallanzani gives the following account of the amours of the water newt, which are the more curious, inasmuch as there is not only no real copulation by the introduction of a male member into the female organs, but not even any conjunction of the bodies, as in frogs and toads. "The male pursues the female, which at first makes a show of flying, but then stops of her own accord. He then approaches her in such a manner, that the lower part of his head comes in contact with the upper part of the head of the female; and this is done while the animals are in such a posture, that their bodies form an angle,

REPTILES.

angle, of which the point is made by the union of the two heads; or they may only join muzzle to muzzle. The bodies are always very near together, so that the angle formed by the two heads or muzzles is always very acute. Then the male erects that dentated prominence, which is placed on his back, and agitates it in a curious manner: he also moves his tail briskly, bending it about, and striking very gently the sides of the female. During this time he emits from the aperture of the anus, now unusually tumid and dilated, a copious jet of semen, which mixes with the water, and thus diluted arrives at the anus of the female, also more enlarged than usual. In this important operation, then, the anus of the male is never in contact with that of the female, which maintains a greater or smaller distance, and never shews any part characteristic of her sex. After the male has discharged this jet of semen, he rests for a while, on some occasions quitting the female; he then returns to his employment, and repeats the contortions of his tail, and the emission of semen." § 80.

In the land newts there is a momentary copulation: "in the clearest days, and in the places most exposed to the sun, the male runs after the female, and when he has overtaken her, he twines himself about her, and unites his genitals to her's, but this union may be termed momentary, after which they part." § 81.

The vehemence of the propensity in amphibia is so remarkable, that they actually will copulate with other species, as frogs with toads, &c. No example of hybrid offspring, from such a conjunction, has been recorded. It has also been known, that frogs, in want of a female, have copulated with other males, or with dead females.

That the animals are entirely absorbed by the powerful emotions accompanying this act is evinced by a series of disgusting experiments of Spallanzani, pursued and multiplied with an unrelenting and unnecessary cruelty, and related quite coolly, without evidence of remorse or the slightest apology. He pricked, cut, and hacked the male frog and toads, without making them loose their hold; amputation of the limbs, and of the head, was equally ineffectual.

Males, after suffering amputation of the fore or hind limbs, renewed their situation, and completed the generative act. "Nay, even the decapitation of a frog did not stop the embraces or fecundation. It is well known, that these animals are so tenacious of life, that that operation does not take it away immediately. That of which I am speaking was thrown into convulsions; but neither the fore-feet nor legs quitted the breast of the female, which brought forth her fetuses in an hour and three quarters, and I was an eye-witness to the male's besprinkling them with semen; that they were fecundated there can be no doubt, since they came to life at the usual time. As soon as he had performed this operation, he deserted his situation, and died in four hours afterwards." *Dissertations*, v. 2. § 90 and 100.

All reptiles may be said to be oviparous; an egg, containing the germ, and as much nourishment as is necessary to support it until it is sufficiently developed to leave this abode, is formed in the body of the mother, and enters the oviduct in all. But there is a subdivision, according to the subsequent progress of the egg thus produced. In the greatest number of reptiles, the ova or eggs are laid by the female in that state, and the young reptiles are developed afterwards: but in some, as the venomous serpents, and the true salamander, the ovum may be said to be hatched in the oviduct, although the animals still come into the world so far enveloped by the membranes, that the character of an oviparous generation is

preserved. The reptiles of the latter kind are called ovoviviparous.

In both these cases, a real egg, like that of birds, is produced, and has no connection with the body of the mother; it is a very different thing from the ovum of the mammiferous animals, in which there is no supply of nourishment for the fœtus; and the latter is connected by the umbilical chord with the vessels of the mother, and derives from this source the materials of its growth. Here, as no true egg is produced in any part of the process, and as the young are always brought into the world alive, they may be justly termed viviparous. See Lacépède, *Hist. Naturelle des Serpens*, t. i. p. 31.

In using the common term ovum, we do not mean to represent that the thing produced is the same in all; nor that it is like the egg of birds in all. There are varieties in the different orders, and, in the batracians at least, there is not a very close analogy to the ova of birds.

The eggs of reptiles are covered with a membranous, rather than calcareous shell; but there is some earthy matter in it. In the green turtle this shell is flexible, but contains earthy particles. It is composed of a soft membrane, containing albumen, which heat does not harden, and a yolk which it does. The eggs of lizards have a more or less hard shell: it is flexible in the grey lizard, hard in the scink mabouya, and the crocodile. It has been asserted, that the eggs of the iguana are not hardened by boiling. The covering of the egg is soft and calcareous in serpents. The batracians lay gelatinous and semitransparent eggs, without any covering.

A part, corresponding more or less closely to the yolk of a bird's egg, is produced in the ovary, escapes from its membranous covering, and enters the oviduct, where it receives its external investment, as the yolk of the bird's egg receives its shell and albumen. In the turtle, the process seems very similar to what we see in birds. There are numerous large yolks observed in the ovarium, contained in calyces; and these, when boiled, are very similar to the yolks of birds. In the crocodile and serpents, it is nearly the same. But in frogs, toads, and newts, the egg in the ovary does not seem to be a yolk, but the rudiment of the tadpole; and it comes forth, surrounded by a quantity of transparent glutinous matter. In the toad and newt, these rudiments are formed into long cords by the glutinous medium, which cords are double in the toad. In the frog they come out separately in so many spheres of the gelatinous matter, about the size of large peas.

In all the reptiles which have a penis, fecundation is effected within the body; but in the batracians, which have no male organ of copulation, it occurs externally. When frogs are joined, it may be seen, that an obtuse, tumid point, occupying the place of the penis, is elongated, and brought towards the eggs nearest the vent. By taking them out of water while this laying is going on, an actual discharge of femal fluid upon the eggs may be seen from this point. In the same way the male of the water newt discharges his fluid into the water near the anus of the female, and thus fecundation takes place. Spallanzani has instituted an immense number of experiments on this subject; they prove, that if breeches be put on the frog, so as to receive the femal fluid, no fecundation occurs; while, on the contrary, the femal fluid from the epididymis, or the juice of the testicles, will produce artificial fecundation of eggs laid by the female after the male has been removed, and otherwise unproductive, or of eggs taken out of the lower part of the oviduct immediately after death. Dilution of the femal fluid, although it diminished the effect of its application,

did

REPTILES.

did not altogether prevent it. When three grains of seed were added to twenty-two pounds of water, some tadpoles were evolved in it, but much fewer than in a stronger mixture.

As fecundation is effected in these animals by the feminal fluid discharged in water, it probably is always produced by an extremely small proportion. Spallanzani has made some calculations, in order to find out the expression in numbers of the quantity of semen that was efficacious in some of his experiments. He mixed three grains of feminal fluid with eighteen ounces of water, and found that a globule, $\frac{1}{3}$ of a line in diameter, taken out of this mixture, was often sufficient to fecundate a tadpole. The ratio of the tadpole to the particles of seed diffused in this drop of water, is found to be as 106,477,777,7 to one. The weight

of the seed is $\frac{1}{199,468,750,0}$ of a grain, and its bulk

$\frac{1}{300,212,042,0}$ of a cubic line. Dissertations, v. i. § 655.

He found, however, that although so minute a quantity of feminal fluid is sufficient to produce the effect, there must be contact of the gross and visible part of the fluid; that no vapour or effluvia, no *aura spermatica* will suffice. Diss. ch. 5. § 161—170.

The seed of one species will not fecundate another; that of the water newt has no effect on the embryos of frogs and toads; nor reciprocally: neither is there any action of the seeds of frogs on toads, nor *vice versa*. § 171—172.

The number of eggs is subject to much variety: it is inconsiderable in the serpents; from ten to twenty in the vipers and lizards; one or two hundred in the crocodile, according to Bartram, Travels in America; two or three hundred in the turtle; but the most numerous in the frog kind. In the toad, where the eggs are laid in a double row, forming a cord of a glutinous nature, these rows measured 43 Paris feet, and contained 1207 eggs. Spallanzani Diss. v. ii. § 45.

In the testudines, serpents, and lizards, which have a true yolk, this is to be regarded as a supply of nourishment for the young animal, whose evolution probably goes on in a manner analogous to what is observed in birds; although the process has not been actually watched, nor the order and succession of the changes observed, as in that class. Blumenbach has delineated the egg of the crocodile, with the young one coming forth; the shell is flexible, as in the other amphibia, and consists of a thick, leathery, and tough, external stratum, marked throughout with extremely fine undulated lines, and lined by a more delicate smooth membrane. The recent eggs, and the young crocodiles which they contain after evolution has commenced, are eaten by various African tribes. The relation in size between the egg (about equal to that of the goose), and the full grown animal (the Nilotic species), which reaches to thirty feet in length, or even more, is at first view remarkable; and Herodotus has called the crocodile the largest animal from the smallest egg. (Blumenbach's Abbildungen, N^o 27.) Seba has also figured a young crocodile, with the membrane of the yolk adhering to the abdomen, as in birds. Thefaurus, t. i. pl. 104, fig. 7.

In the animals just enumerated, the eggs, whether deposited in the sand of the sea-shore, or of the banks of rivers, in the holes of trees, the chinks of walls and rocks, &c. undergo no process of incubation like those of birds, but are developed in the ordinary temperature of the atmosphere, and the young animals come forth from their confinement, differing only in size and proportions from their parents.

In the venomous serpents, and the salamanders, the case is different. The egg containing, as in the preceding instances, the young animal, and a sufficient supply of nutriment for its growth, until it is of size to quit its original abode, is hatched in the oviduct of the mother, and the young come forth from the cloaca alive, but surrounded by their membranous coverings. The young vipers and other venomous serpents, when they are born, are freed by the mother from this kind of after-birth.

A very curious circumstance has been observed in some of these, recalling to our minds the abdominal pouches of the marsupial mammalia, and the mode in which they serve as a shelter for the young, while yet too small to shift for themselves. Palisot Beauvois thus relates the fact we allude to. "Having perceived a rattlesnake at some distance, I approached as gently as possible, when, on lifting my hand to strike him, he founded his rattle, opened his mouth, and received into it five small serpents, about the size of a quill. I retreated and concealed myself, when the animal, thinking the danger at an end, opened his mouth, and let out his progeny. When I appeared again, they immediately took to their same retreat." He had heard this fact from American planters, and it has been since confirmed by other travellers. Daudin, Hist. Nat. des Reptiles, v. 5. p. 68.

The young of the salamander, like those of the viper, are born alive. The female brings forth very delicate oval vesicles, which may be compared to hydatids, each of which contains a perfect young salamander, an inch in length, moving its tail, and lacerating its coverings at the time of birth, and emerging in the form of a four-footed tadpole.

"In this same strange animal," says Blumenbach, "I have observed a curious fact, already noticed by Wurffbain in his Salamandrologia, p. 83. *viz.* that a female, kept by herself, and absolutely without intercourse with any other of her kind, has produced young ones. I have kept in a glass at home, for five months, a female salamander, whose tail I had cut off, and in the mean time have had no other in the house, nor even seen one. Yet this solitary female, which, to my surprise, sustained so long a fast without growing thin, has begun within a few days to bring forth young, of which thirty-four are now before me, not only living, but very lively. This observation will lead us to two conclusions; 1st, that salamanders really copulate, and that the male does not fecundate the ova as they are discharged, like what we have described in the case of the water newts: 2dly, that salamanders have the same nature in this respect as hens; which, when they have been once impregnated by the cock, will lay fruitful eggs, not for a whole year, as Fabricius ab Aquapendente asserted, but, according to the most accurate researches of Reaumur (art de faire eclorre les oiseaux domestiques, t. 2, § 327), for five weeks after separation from the male.

These young salamanders have a two-edged tail, broadly pinnated on each edge, excellently adapted for swimming, and furnished on each side of the neck with imbricated branchial appendages like those of the tadpole, which however soon disappear, the two-edged tail being at the same time converted into a cylindrical pointed one." Specimen, &c. 34.

All the reptiles of the frog and toad kind, and the aquatic salamanders, have this remarkable peculiarity, to which nothing at all analogous has been observed in the economy of the warm-blooded classes or the fishes: *viz.* that they undergo a metamorphosis; and have, in their two states, not only an altogether different external form, but also important differences in many of the great internal organs. In their first state, they are little aquatic animals with tails

REPTILES.

and large heads; from their twisting movements of the former, and the great size of the latter, they have been called in Latin *gyrini*, in French *têtards*: the English name is tadpoles, and the German *kaulquappen*.

Development of the Frog.—As the spawn of frogs is deposited in ponds, ditches, or other stagnant water, the contained ova are evolved in the ordinary temperature of the atmosphere. In one species of toad, Spallanzani says, that it proceeds at 6° above freezing of Reaumur. He found that a temperature of 111° Fahrenheit, did not interfere with the subsequent evolution; that the number of tadpoles produced was much diminished after exposure to 122°; and that very few were evolved after the eggs had been immersed in water of 132°. A heat of 111° was fatal to tadpoles and frogs; although the latter bear 111° in the warm springs of Pisa. (Tracts, vol. i. p. 32.) Each egg lies in the centre of a transparent spherical mass of mucilage; many of which, aggregated together, form what is called frog's spawn. Round the eggs are two concentric membranes, of which the innermost, when pierced with a needle, discharges a fluid as limpid as water. The egg is round, and has a smooth surface, of which one hemisphere is black, and the other white. When the hot season is far advanced, the observer soon perceives the lineaments of the tadpole. The egg grows for some hours without losing its round shape: it is next elongated; the white hemisphere becomes darker, and the black changes into a longitudinal furrow, terminated by two perpendicular processes. And, as it increases in bulk as well as length, the internal circular membrane is dilated, and contains more fluid. By tracing thus the progress of the evolution, we come to perceive that these bodies are not eggs, as naturalists suppose, but real tadpoles. The furrow and the processes become longer; the supposed egg assumes a pointed figure, the whitish hemisphere dilates, and the black is incurvated. The pointed part appears to be the tail of the tadpole, and the other the body. Further, the opposite end takes on the appearance of the head, in the fore part of which the form of the eyes is visible, though they are yet closed. The two processes also, by which the animal fastens itself to bodies, when it is tired of swimming, become evident, as likewise the vestige of the aperture of the mouth, and the rudiments of the gills. As the organs are further unfolded, the tadpole, which has not moved hitherto, begins to stir, and loosen its fetters; at this time it appears clearly, that the internal circular membrane is the amnios, in the liquor of which the tadpole floats; the umbilical chord at last is seen, and becomes still more visible the first day after the animal has quitted his confinement. The cord is not, as in other animals, attached to the belly, but to the region of the head. (Spallanzani's Dissertations, v. 2. § 14—16.) We take the liberty to note what is here said about the umbilical cord as a subject for further research.

The branchiæ are visible towards the end of the sixth day: in the course of the seventh and eighth all the tadpoles quit the viscid substance, which had been floating on the water, and which had hitherto served them for food. By the fourteenth and fifteenth days they are so much grown, that two small but prominent eyes, an open mouth, nostrils, &c. can be distinguished. About the nineteenth and twentieth days the branchial appendages are withdrawn within the skin, and no longer visible. The heart can be seen to move, and the caudal vertebræ are recognisable. On the twenty-fourth day the front limbs, which had already existed under the integuments, appear in the place of the branchiæ, or rather near where they had been. In ten or twelve days more the hind limbs come out. In this state they swim

about in the water, and grow. The tail gradually disappears, and in about two months after they have been hatched, they are metamorphosed into frogs. These at first are small, and then become gradually larger. Except in the case of the *rana paradoxa*, and the *bufo fuscus*, in which the tadpoles become so large, that the animal, when it has changed, is of the adult size.

Anatomy of the Tadpole.—The points in which the animal differs from the organic arrangements of its perfect state, are the large tail, which bears a very considerable proportion to the body, and is afterwards entirely lost; comparative smallness of the mouth, to the under lip of which a small organ is attached for fixing the tadpole to other objects; a kind of horny plate for jaws; two tuberosities under the neck, which the animal can distend at pleasure; the rudiments of the lungs; the intestines convoluted in a spiral mass, which swells the abdomen, and far exceeds, in its ratio to the length of the body, the intestinal canal of the perfect animal; the branchial appendages, and the vessels connected with them; the fore limbs, situated at first under the skin. For the series of changes, and the anatomy of the young animal, see the plates of Roefel, Hist. Ranar. Noftrat.

Further particulars of the anatomy of tadpoles, and particularly of the circulating and respiratory organs. In his "Recherches sur les Reptiles douteux," Cuvier has entered at some length into a consideration of the anatomy of the tadpole. The following account, which is translated from his memoir, as published in the "Recueil d'Observations de Zoologie et d'Anatomie comparée, faites dans le Voyage de Humboldt et Bonpand," v. 1. p. 195, is to be understood as applying to the full grown tadpole.

The tadpoles of frogs, tree-frogs, and toads, differ from those of salamanders, principally in having their branchiæ concealed: we have already observed, that in their earlier stages the branchiæ of the former are also external: the only way by which the water can escape from them is through two holes, formed in different situations, according to the species: there are even several which have only one hole, on the left side. Such are the tadpoles of the jackie (*rana paradoxa*), and of the brown toad (*bufo fuscus*); but the tadpole of the common frog has two, both placed below.

We find, on opening the skin of a tadpole longitudinally, that the internal organs are divided into two parts, or contained in two membranous sacs.

The first extends from the horny and false jaws, which form the mouth of the tadpole, to behind the branchiæ, enveloping the latter entirely. The other contains the abdominal viscera; it is the peritoneum, on which vestiges of the abdominal muscles are already visible.

The first sac is very thin and transparent, and penetrated, like the skin, by holes for the exit of the water from the branchiæ.

The latter form on each side four transverse rows of small tufts or fringes, supported by the same number of small cartilaginous arches, which are marked on the side next to the mouth by small rounded tubercles. These cartilaginous arcs are articulated on one side behind the cranium, on the other to a species of os hyoides, and have the same motions as in fishes. In their intervals the water can pass freely from the mouth to the branchiæ, to be discharged subsequently through the small external apertures.

The organization of the branchiæ in the tadpoles of frogs is, therefore, the same as in certain fishes, for example the callionymi and others, where the water can only pass out by narrow apertures: there is, however, this difference,

REPTILES.

that they are not covered, either by a branchial operculum, or by radiated bones.

The branchiæ, or gills, properly so called, that is, the immediate organ in which the pulmonary vessels are distributed, are small tufts formed like feathers, that is to say, fringed on the two sides. Each cartilaginous arc supports about thirty such; and in the middle of each tuft are its two principal vessels derived from the two great blood-vessels of the arc.

It may be observed here, that the fishes called syngnathi have also their branchiæ in the form of tufts.

The heart, placed in front of this apparatus, and receiving the blood from the body by the vena cava, which comes, as in most cases, in great part through the liver, has only one auricle and ventricle, as in fishes, and in adult frogs and salamanders, without any of those divisions which are observed in the chelonian and saurian orders. The ventricle gives origin to a single artery, which is completely distributed on the eight branchiæ, so that no drop of blood can go to the rest of the body, without having passed through the respiratory organs. All the blood which has circulated through the gills, is collected in the branchial veins, which go towards the back, and are united into a single trunk, which becomes the descending artery: but, before uniting, they furnish arteries to the head, fore feet, lung, and liver; so that in the tadpole, the lung receives blood which has been already exposed to the action of water; and this small portion of the animal's blood undergoes respiration twice, while, with respect to the great mass of the fluid, there is only one respiration, and that of an aquatic nature, or similar to the respiration of fishes.

Great changes take place when the tadpole becomes a frog; but they are produced by very simple means. As the arms and head increase in size, their arteries are enlarged; the branchiæ, on the contrary, are obliterated, and their arteries are gradually reduced: but, as it is always necessary that blood should go to the head and other parts, one of the four principal branchial arteries on each side is enlarged, and serves to convey it. Then the artery, which goes out of the heart, and was formerly divided into eight branches, is now simply bifurcated, and its two branches supply the arterial trunks of the head, arms, lungs, &c.; and lastly, are united to form the descending aorta. Now this is precisely the circulation of the frog, in order to produce which it has been merely necessary to obliterate six of the branchial arteries of the tadpole, and to enlarge the two others. Henceforward the lungs are the exclusive seat of respiration, receiving, however, at each pulsation, only a small portion of the whole mass: the frog, therefore, is now an aerial animal in respect to its breathing.

While these changes are going on in the respiratory organs, several others are taking place in different parts of the body. The narrow horny bill, preceded by small fleshy lips, falls off, and its muscles disappear; the jaws grow hard, and form a much more ample mouth.

The eyes, disengaged from that skin, which only allowed them to appear through a transparent disk, are now seen with their complicated apparatus of three eye-lids.

The fore-feet, which had been concealed between the bag enclosing the branchiæ and the peritoneum, appear externally; the hind-legs grow every day larger; and the long tail, formed by so many muscular strata, and supplied by such numerous vessels and nerves, begins to disappear. The intestines, formerly of nearly uniform size throughout, excessively long and arranged in a spiral mass, become short, and are dilated at proper parts to form a stomach and colon.

Among these changes, which convert the tadpole into a frog, we cannot enumerate the appearance of the generative organs. The tadpole already possesses testicles, ovaries, and their fatty appendages; and if these parts are not so large as in the frog at the season of reproduction, they approach nearly to their size at other times of the year.

What we have just said concerning the tadpole of the frog is equally applicable to that of the toad; but the different species exhibit considerable varieties in the epocha and the size at which the change occurs, as well as in the rapidity of the change. The jackie (*rana paradoxa*) loses its tail very late, and long after its branchiæ; while the latter do not entirely disappear until it has reached the full size of its perfect state: the pipa, on the contrary, loses both very early, and while it is still very small. The species which lose their branchiæ late, are larger in the tadpole than in the perfect state, because these supernumerary organs swell out the front of the body, while the tail prolongs it behind. They seem, therefore, to become smaller under their metamorphosis, and grow no more when they have become frogs. On the other hand, those which lose their tail and branchiæ early, have still a long time to grow, and may be seen of all sizes in the perfect state. This has given rise to the mistaken notion that the jackie is changed into a fish; the tadpoles being larger than the adult frogs, it was not thought possible that the latter could be the second state.

We might restore to the larvæ of the salamanders the name of *cordyli*, which they bore among the Greeks, according to the remark of Schneider. They ought not at least to have that of tadpole (*têtard*), because they have not a large head, their branchiæ not being concealed under considerable coverings, but floating loosely on the exterior of the body. They are tufts arranged like the teeth of combs, simply fleshy or membranous, and attached by pedicles, which allow them to float loosely in the water. The cartilaginous arcs of the sides merely serve to limit the small apertures through which the water passes out of the mouth; for, although the form and arrangement of the tufts seem to expose them sufficiently to the action of water, there are still openings from the mouth, enabling the animal to establish a current of the fluid. In other respects, the circulation is carried on as in the branchiæ of the tadpoles of frogs, and it undergoes the same changes when the branchiæ are obliterated.

The larvæ of salamanders, observed by Cuvier, had the same viscera as the adult animals, and possessed no horny bill, although their branchiæ were still very complete. He therefore concludes, that in this respect, as well as in their feet, and in the organization and permanence of their tail, there is a much more close resemblance between these larvæ and the adult salamanders, than between tadpoles and frogs.

These remarks on the anatomy of the tadpole, and of the larvæ of salamanders, are illustrated by four figures in the 13th plate of the work quoted above. Figs. 1, 2, and 3 represent the anatomy of the tadpole of the *bufo fuscus*; and fig. 4. that of the larva of the *salamandra aquatica*.

The co-existence in the same animal of branchiæ and lungs, that is, of organs calculated for breathing air, and of those which are fitted to extract air from the water, is not peculiar to the larvæ of frogs and salamanders; it is observed also in the *serp lacertina* and the *proteus anguinus*, two animals whose construction is in many respects so singular, that the opinions of naturalists concerning them have been long extremely unsettled. Many have supposed them to be the larvæ of some large reptiles, for which opinion, other

REPTILES.

other circumstances in their organization and habits, besides the possession of branchiæ and lungs, have been adduced as arguments. Others have contended that they are perfect animals; and the more exact researches of modern naturalists and anatomists seem to have finally proved that this is the case. The anatomical details, by which this conclusion is supported, will be found towards the end of the article.

As the firen and proteus, truly perfect animals, have been sometimes considered as larvæ or imperfect states of unknown reptiles, so the contrary error has been committed, of describing the larvæ of known species as perfect animals allied to the firen and proteus. Laurenti, one of the first naturalists who endeavoured to reduce the class of reptiles to regular order, established a genus (*proteus*) for such batracian reptiles as, according to him, possessed both branchiæ and lungs. To this genus he has assigned the tadpole of the *rana paradoxa*, under the name of *proteus raninus*; and another, which he himself inspected, and which has since been ascertained to be the larva of an aquatic salamander, under that of *proteus tritonius*. (See his *Specimen medicum exhibens synopsin reptilium*.) The firen *operculata* of M. de Beauvois (*Transactions of the Philosophical Society of Philadelphia*, vol. iv.) is considered by Cuvier as a similar instance, and perhaps as the very axolotl or Mexican animal, which will be described presently. He regards, in the same light, an animal described by the very learned writer on amphibia, Mr. Schneider, as found in the lake Champlain: see *Hist. Amphib. Nat. et Litter. Fascic. 1. p. 50*. He says it may be objected that we cannot easily conceive that so complicated an apparatus as that of the branchiæ, their cartilaginous arches, and the muscles moving them, should disappear and leave no trace behind; but, as the larvæ of our salamanders experience such a change, the singularity of the phenomenon cannot be pleaded as an objection to it. *Recherches, &c. p. 117*.

Anatomy of the Axolotl, or large Mexican Salamandrine Tadpole.—Another animal of this kind is one found very commonly in the lake surrounding the city of Mexico, and noticed by the early writers in their accounts of those countries, and of the interesting objects they produce, although not methodically described or scientifically investigated until very lately. Hernandez speaks of it in two places; in one, under the name of the eatable tadpole (*gyrinus edulis*), or *atolocatl* (*Hist. Anim. Miner. Nov. Hisp. lib. unic. Tract. 5. cap. 4. p. 77*: this book is placed at the end of the abridgement by Recchi); in the other, under that of *lusus aquarum, piscis ludicus, or axolotl* (*ibid. cap. 2. p. 76*, and in the large abridgement by Recchi of the whole work of Hernandez, lib. 60. cap. 4. p. 316.) This account, accompanied by a figure of some other animal, was copied into other works with various errors.

Dr. Shaw described an individual sent immediately from Mexico to the British Museum, and gave two good figures of it; in the *Naturalist's Miscellany*, N^o 343, under the name of *gyrinus mexicanus*; and in the *General Zoology*, vol. 3. pt. 2. pag. 612. pl. 140, under that of firen *pisci-formis*, considering it as allied to the genus firen.

Mr. de Humboldt met with it in Mexico, and recognized it as the axolotl of the Mexicans and first Spaniards, under which name it is still known. He brought specimens of it to Europe, and entrusted their anatomical investigation to the experienced hand and profound judgment of Cuvier, whose description we extract from the *Recherches sur les Reptiles douteux*, already quoted, pag. 109. et seq. pl. 12.

Anatomy of the Axolotl.—In its size and general configuration it very closely resembles the salamander terrestris (*lacerta salamandra*) of Europe. No one would hesitate

in calling it a salamander, were it not for the branchiæ, which latter resemble very narrowly those of the larvæ of salamanders, and float loosely at the sides of the neck.

The openings communicating with the mouth are four in number, and much larger than in the firen. A fold of the skin of the head forms a species of operculum for the four. There are four arches, as in fishes, and we should hence expect five openings, but the fourth is immediately united to the trunk. The two intermediate arches have, towards the mouth, two rows of pointed denticuli; but the first and fourth possess, each, only a single row. None of these denticuli exist towards the operculum, so that the first of the four openings is not denticulated in any direction. Each of the four arches has, towards the outside, a sharp membranous crista, which might deceive superficial observation by causing a resemblance to the gills of a fish; but there is no vascular net-work for respiration, and the arterial trunks follow, without any division, the three first arches to arrive at the branchial tufts, which are the only true gills. There are three of these tufts on each side, attached to the three first arches, where the skin joins them together; the operculum and the fourth arch have none. These tufts are much more ramified than those of the firen, but their ramifications resemble a lock of hair, and are not arranged with so much regularity.

Osteology.—The head is the same as in the salamanders, except that the cranium is rather broader. The teeth are placed in the same way on the edges of the jaws; there are moreover two plates immediately behind the edge of the upper jaw; but the two longitudinal series, which are observed along the palate of the European salamanders, could not be perceived. The head is articulated in the atlas by two condyles, as in the firen and salamanders.

The apparatus for supporting the branchiæ is very similar to that of the firen; and, at the time of the metamorphosis, a part of it probably remains to form the os hyoides of the salamander. The middle piece is cylindrical, short, and terminated behind by a forked extremity. The front end supports two cartilages, the ends of which, suspended to the angles of the jaw, correspond to the hyoideal branches of fish: they are immediately under the membranous operculum. From the posterior end of this middle piece proceed two other branches on each side; a broad one supporting the first cartilaginous arch, and a more slender one trifurcated to support the three other arches. The four branchial arches are suspended, by their outer extremities, to the first vertebra.

There are seventeen vertebræ from the head to the pelvis; and twenty-three from the latter to the end of the tail. The spinous processes of both are longer than those of the salamander; and they exist on both aspects of the caudal vertebræ, which makes the vertical measurement of this part exceed that of the European aquatic salamanders.

There are thirteen small ribs on each side, similar to those of the salamander.

The osteology of the limbs resembles in all respects that of the salamander, excepting the more pointed form of the last phalanges, which has occasioned them to be taken for nails.

Organs of Sense.—The eye is smaller in proportion than in European salamanders; but not smaller than that of the species brought from the Alleghany mountains by Michaux.

Organs of Circulation.—The vena cava receives the termination of the veins of the head; of the branchiæ, and their arches; of the lungs; of the fore-feet; lastly, of the inferior vena cava, which has traversed the liver, and received, as

REPTILES.

usual, the blood of the vena portarum. It enters a large and single auricle; there is also a single ventricle, giving origin to a large muscular artery, similar in all points to that of fishes, of the furen, and of tadpoles. It produces for the branchiæ three arteries on each side, which proceed, as we have already mentioned, along the three first arches. The branchial veins are quickly united behind into a single trunk, under the back of the head, and this vessel, following the direction of the spine, becomes the great artery of the body. This is exactly the circulation of the batracian larvæ; and the axolotl, being larger than any of the European species, affords a convenient opportunity of examining this kind of arrangement in the circulating organ.

Organs of Respiration.—The branchiæ of the axolotl, exhibiting on a larger scale the same motions as those of the salamandrine larvæ, the mechanism can be better understood; and the following description of the muscles will, therefore, be received with interest.

Each of the cartilages analogous to the hyoideal branches has a very strong muscle, descending from the basis of the skull along their convex sides to their inferior extremities. These muscles open the branchial arches, by separating their inferior extremities from the palate.

The arches are approximated by a muscle fixed behind to the inferior extremity of the last, advancing under that of the three others, and giving a slip to each. Its antagonist is a small muscle, fixed, on one side, to the inferior extremity of the hyoideal branches; and proceeding backwards as far as under the first branchial arch, to which it is attached, opposite to the slip of the preceding.

The os hyoides is carried forwards by two genio-hyoidei, and backwards by two pubio-hyoidei: which latter supply the place, as in the salamanders, both of the sterno-hyoidei and recti abdominis. It is elevated by a muscle similar to the mylo-hyoideus of the same animals.

Lastly, the three tufts are themselves elevated and depressed by as many pairs of muscles, which are attached above and below to the convexities of the branchial arches, and have their other fixed points in the bases of the tufts.

The lungs are two large bags, on the internal surface of which the blood-vessels form a loose but very conspicuous net-work. There are no cells. They open into a common, membranous, opaque, and tolerably wide canal, supplying the place of trachea, but unfurnished with cartilaginous rings, and contracted to form a small larynx with two membranous lips. The glottis is small, formed by two membranous projections, behind each of which is a small hollow or ventricle, which may be supposed to produce a more powerful voice than that of the furen.

Organs of Digestion.—The tongue possesses but little power of motion; it is free in front, but fixed behind to the anterior extremity of the os hyoides.

The œsophagus is short, folded longitudinally, and continuous with the stomach, which is large and membranous, but considerably narrowed, and more muscular towards the pylorus. It was filled, in the two individuals from which this description was drawn up, with fresh-water cray-fish, like the European, which had been swallowed without mastication, so that entire limbs were found even in the rectum.

The intestinal canal is tolerably large, particularly behind, and of moderate length. It makes two principal folds, and has neither cæcum nor any internal valve. The liver is rectangular, without any deep notches; no gall-bladder was observed. There is a small spleen in the centre of the mesentery, which is simple, as usual.

All these intestines are like those of the salamander.

Generative Organs.—The ovaries, small, flaccid, and hardly

containing visible ova, resemble, in their situation and fatty appendages, those of the salamander. The oviducts were so delicate, that they could scarcely be seen.

From all the circumstances just detailed, and from the close resemblance of all its organs to those of salamanders, and their larvæ, we may conclude, that the Mexican axolotl, or furen pisciformis of Shaw, is the larva of some large salamander.

Growth.—The age of puberty seems to be the limit of growth in many of this class, as in birds, and we may almost say, in all mammalia. But others, particularly the crocodiles, turtles, and serpents, grow constantly; of which continual increase the whales seem to afford an example among mammalia; at least, no limits can at present be assigned to their stature. We know little about the length of life of the amphibia. Many, particularly the tortoises, serpents, and crocodiles, are prodigiously long-lived; coming forth originally from an egg, which is very small in comparison to their future stature, growing very slowly, and reaching an immense size. Niebuhr saw at Surat a tortoise 125 years old.

Organs of the Animal Functions.

Organs of Motion. Description of the Bones.—We know of nothing peculiar in the organisation of the bony substance of reptiles. In the larger species, the bones possess as much firmness as in the mammalia; but in the smaller, as the frogs for example, they are more cartilaginous. Cuvier states, in general, that the bones of reptiles contain more gelatine than those of the mammalia. Caldesi asserts, that there are no medullary cavities in the tortoise; according to Cuvier, there are considerable ones in the crocodiles. *Leçons d'Anat. Comp.* tom. i. p. 110. They have never been seen tinged with madder.

The Head.—A very diminutive cranium, and enormous jaw, make up the head in this class.

As the brain of reptiles and fishes occupies only a small part of the cavity of this cranium, no important consequences can be deduced from its shape and size. In the tortoise, this cavity is large, narrow from right to left, elevated anteriorly and depressed posteriorly. Its lateral parietes are almost vertical, and its base is parallel to the palate. The external form of the head, and its apparent magnitude, are occasioned by the accessory bones, between which and the cranium there is a large space occupied by muscles and glands. The greatest part of the skull is occupied by the large lateral hollows, holding the eye, and the powerful muscles, that move the lower jaw.

The small size of the cavity of the cranium, with respect to the external bulk of the head, is still more extraordinary in the crocodile. In an individual four metres long (between thirteen and fourteen feet), that cavity will hardly admit the thumb, and the area of the section of the cranium is not one-twentieth part of that of the whole head. (See a section of the skull of a crocodile in the *Annales du Muséum*, tom. x. pl. 4. fig. 5.) The length of the cranium is not one-fifth of the length of the head in the gavials (*longirostres*, Cuvier); and it is less than one-fourth in the alligators or caimans (*alligatores*, Cuv.), and in the true crocodile (*crocodili*, Cuv.) The figure of the section is oblong, rather larger anteriorly, and descending posteriorly. There is a considerable depression for the pituitary gland. Its breadth is equal to its height; and the lateral parts of the head, as in the tortoise, cover only the temporal fossæ.

The relative size of the cranium and jaws undergoes a very remarkable change, in proportion to the gradual development of the crocodile. The head, when it comes out of the shell, is thick and rounded, and the forehead prominent; see

Seba,

REPTILES.

Seba, *Thefaurus*, tom. i. pl. 104, figs. 3 and 6; and Blumenbach's *Abbildungen*, N^o 27. The eyes are now equidistant from the end of the snout, and the posterior extremity of the head; of which the cranium forms nearly one-third. When we look at the adult animal, we are astonished to find the frontal prominence gone, leaving the head quite flat, and the jaws so elongated, that the eyes are three times farther from the end of the snout than from the back of the head; and the proportion of the face to the cranium is 20 instead of 3 to 1. Geoffroy St. Hilaire in the *Ann. du Mus. voi. x. p. 77.*

The cameleon exhibits also a great disproportion between the cranium and the rest of the head. Its brain, according to the description of the Parisian dissectors, does not seem larger than a pea; and the remainder of the head, which is of considerable size, consists of the large maxillary bones, the orbits, and immense temporal fossæ, which, not being separated by any partition, give the cranium a very singular appearance. Description *Anat. d'un Cameleon, &c.*; or *Blasii Anat. Anim. vol. i. p. 14.*

The cranium of frogs and salamanders is almost prismatic.

The French naturalists have furnished excellent descriptions and engravings of the heads of various crocodiles. It will be as well for us to enumerate here the sources of information concerning the osteology of this animal altogether, and to give a few references to good figures of the skeletons of other reptiles.

There are tolerably good representations of the crocodile's skeleton (the East Indian) in Grew's *Museum Societatis Regiæ*, and in Faujas St. Fond, *Histoire de la Montagne de St. Pierre de Maestricht*, pl. 44. The head of the crocodile of the Nile (*croc. vulgaris*, Cuvier), is figured by Geoffroy in the *Annales du Museum*, vol. ii. pl. 37, fig. 2. In pl. 4. vol. 10. of the same work are four figures of the skull to illustrate a paper of Geoffroy St. Hilaire, entitled "*Determination des Pièces qui composent le Crane des Crocodiles*;" and pl. 1, of the same volume, contains nineteen figures of the heads of various crocodiles in different views, to illustrate Cuvier's paper "*Sur les différentes Espèces de Crocodiles vivans & sur leurs Caractères distinctifs*." In the 12th volume of the *Annals*, Cuvier has given his "*Observations sur l'Osteologie des Crocodiles vivans*," with two plates, in which most of the bones are carefully figured. For the skeleton of the tupinambis, see Cuvier, *Leçons*, v. 5. pl. 3; of frogs, Roefel, *Historia Ranarum Nostratum*; of the salamander, Latreille, *Hist. des Salamandres de France*; of the tortoise, salamander, frog, cameleon, lizard, and a serpent, Daudin, *Hist. Nat. des Reptiles*, vol. 1; of the proteus, firen, and Mexican axolotl, Humboldt, *Recueil d'Observ. de Zool. &c. t. 1*; of the tortoise, *Blasii Anatomia Animalium*; Cuvier, *sur les ossemens fossiles*; and Geoffroy St. Hilaire, *sur les tortues molles*, in the *Annales du Museum*, vol. 14. The skeleton of the tortoise is also figured in *Chefelden's Osteology*; in *Coiter's Lectiones Fallopii de Partibus similaribus*, fol. Norib. 1575; and in *J. D. Meyer's Zeitvertreib mit Betrachtung curioser Vorstellungen allerhand Thiere*. t. 1. tab 29, 31; t. 2. tab. 62; and the separate parts in *Caldesi osservazioni anatomiche intorno alle Tartarughe*. Firenze, 1687. The skeleton of the common green lizard may be seen in *Coiter*, pl. 4; in *Meyer*, t. 1. pl. 56; that of the salamander and water newt, and of several snakes in *Meyer*: that of the cameleon is prefixed to *Chefelden's 6th ch.* *Schneider* has figured that of the *rana pipa* in his *Hist. Amphib. fascic. 1.*

For the form of the head in the different species, a point belonging rather to natural history than comparative ana-

atomy, we must refer to the figures already quoted. The surface is more or less rugous in different specimens; and in many very considerably so; these differences are specific, only where individuals of the same age are compared, for the rugosities increase in size and prominence in each species with the increase of years. The bony substance is often perforated by many small holes, as if it were carious or worm-eaten. The futures are constant; they are not effaced in the oldest heads observed by Cuvier.

The Cranium.—The cranium of the crocodile, viewed from behind, has the form of a very irregular truncated pyramid; of which the point or narrowest portion is downwards, and the base excavated to lodge the brain, is upwards. This pyramid has three surfaces, one posterior, which forms the occiput, and two lateral. The occipital surface is almost triangular; one of the angles (the apex of the pyramid) is inferior, the other two are superior, and greatly prolonged backwards and to the side, in order to form the enormous articular processes, which receive the lower jaw. Their position is almost horizontal. The foramen magnum is situated in the middle of this surface, and under it the single condyle for articulating the head with the vertebral column.

The futures depart from the foramen magnum, which divide the occiput into particular bones. The superior part of the cranium is formed by a single parietal bone. Anterior to it there is an os frontis, also single, which forms the roof of the orbits.

The ossa temporum are situated on each side of the parietal bone, and are partly supported by that articular process for the lower jaw, already mentioned.

A small arch on each side, different from the zygoma, leaves between it and the parietal bone a large round hole, which perforates the temporal fossa. The arch is partly formed by a process of the os temporum, and partly by a particular bone articulated to the junction of the parietal and frontal. The particular bone occupies the place of the post-orbital process of the os frontis in the mammalia; for it descends behind the orbit to join the cheek-bone; and with it finishes the frame of the orbits.

The unusual configuration of the whole head in the crocodile necessarily involves very extraordinary modifications of the individual bones, which it is in many cases exceedingly difficult to refer to their corresponding ones in the crania of the mammalia. For a more minute account of this matter, which could not be easily understood without plates, we refer to the memoirs and engravings, already quoted, of Geoffroy and Cuvier.

A cranium similar to this of the crocodile, is found in the other lizards, notwithstanding the great differences in the form, proportion, and the direction of the parts. In the cameleon, therefore, the foramina, by which the temporal fossa communicate with the cranium, are so large, and the bony edges which form them so thin, that the latter represent three slender branches rising to support the kind of helmet which distinguishes this animal. The articular processes are not directed backwards, but downwards.

The last peculiarity is also observed in the other lizards, but they have not the crests of the cameleon, and the upper part of their cranium is broad, like the crocodile.

In frogs and salamanders the cranium is nearly of a cylindrical form, flat superiorly, and enlarged posteriorly; the frontal bones have the shape of an elongated rectangle, and occupy the interval of the orbits. The Surinam toad has the cranium much flatter than the other genera.

The eminences intended to assist in the articulation of the jaw are turned directly towards the sides.

The structure of the cranium of tortoises bears more resemblance to that of crocodiles than of frogs. The frontal bones form only the roof of the orbits, and the cranium does not pass between these cavities. They are very short, and the parietalia are three times longer. The latter are not confined to covering the cranium. They extend on each side, and form an arch over the temporal fossa. In the sea tortoises this arch is completed by two peculiar bones, which extend from the os parietale to the zygoma, and the anterior of which bounds the orbit behind.

The articular processes are directed downward, as in theameleon. Above these and the meatus auditorius, we find considerable mastoid processes, which are pointed superiorly in land tortoises, but are rounded and marked by a longitudinal furrow in the sea tortoises.

Serpents have two frontal bones almost square, and a single parietal bone. Their cranium advances forward between the orbits, as in frogs. The occipital bone has a process directed backward, and connected with a particular moveable bone, analogous to the square bones of birds, to which the lower jaw, and the arches which form the upper, are articulated.

The general form of the cavity of the cranium of reptiles is oblong, and almost of an equal breadth, being merely a little contracted between the ears. The tortoise has a kind of sella turcica, the four clinoid processes of which are directed forward. The sphenoidal fossa is somewhat depressed in the serpents, but it has no clinoid processes. It is a semilunar depression, the plane of which is situated from before backwards.

The basilar fossa is lower than the other fossæ in the crocodile, and in some tortoises.

Foramina of the Cranium.—The interior part of the cranium is frequently not closed by ossification in reptiles and fishes, and the olfactory nerves pass through a large vacant space, which is not subdivided into particular holes. This at least is the case with theameleon, the iguana, tortoises, the pike, the anarrhichas, &c. In others, the olfactory hole is contracted, but is still simple, as in the crocodile. It is double in frogs and salamanders. The rays and the sharks have also two holes, which are considerably removed from each other.

The optic holes are likewise sometimes united into one, as in the crocodile: those of the tortoise are much removed from each other, and are distinguished from the great hole in the front of the cranium, by only a small bony partition. The structure of the cranium in the pike is similar. In the frogs, the rays, the anarrhichas, and it should seem in the greater number of fishes, the optic holes are at a great distance from each other, and perforate the sides of the cranium. These animals have no sphenoid-orbital fissure, and the small nerves transmitted to the eyes pass each through a particular foramen.

There is, in general, only one hole on each side for the three branches of the fifth pair of nerves, which, therefore, supplies the place of the foramen rotundum, foramen ovale, and in part of the sphenoid-orbital fissure. This hole, however, is divided into three in the carp.

The meatus auditorius internus exists in reptiles.

The Face.—In the crocodile the face resembles one-half of a cone irregularly flattened on its convex surface. It is chiefly formed by two ossa maxillaria, and two ossa nasi, which are situated almost parallel to each other, and two ossa intermaxillaria, which form the end of the muzzle, and surround the aperture of the nose like a ring.

The bones analogous to the lacrymalia are four in number, two on each side. The os malæ, which is very large,

after forming the inferior, and affording a small process to the posterior edge of the orbit, extends directly backwards to join the great mastoid protuberance: thus the temporal fossa has no communication outwardly, except by a hole which is smaller than the orbit, and the greater part of which is covered by these bones, as by an arch.

The nasal fossæ are continued in a long and narrow tube under the foramen magnum. They perforate the ossa palati, and a particular bone which is analogous to the pterygoid processes of the os sphenoides. This bone is situated almost precisely under the cranium, and is enlarged on each side until it forms a kind of square and almost horizontal wing. An osseous branch unites it laterally to the os maxillare and os malæ, in such a manner that a large hole is left on each side of the arch of the palate.

In theameleon the face is concave superiorly, and bordered by a serrated ridge throughout the whole of its circumference. We observe two holes which communicate with the orbits, and two other oval foramina, which correspond to the incisive holes in the palatine surface. The bones which compose the face are nearly the same as those of the crocodile. The other lizards exhibit still less difference.

The frog and the salamander have the nasal and intermaxillary bones very short, and broader than long, which renders their face round anteriorly. The os maxillare is very narrow, and is scarcely contracted in forming the zygomatic arch. The orbits are large, but have no inferior surface, and therefore communicate with the palatine fossa. The ossa palati form the anterior edge of the orbital fossa inferiorly. They resemble portions of a circle. They are furnished with pointed teeth on their circumference. The canal of the nares is very short in the salamander. There is only a simple hole in the frog.

The face of the Surinam toad is very flat, but the bones are the same as in the frog. The orbital fossæ are oval, and no aperture similar to the canal of the nares can be distinguished.

The face of serpents is rounded nearly in the same manner as that of lizards. Between the os frontis and os parietale, there is a particular bone which terminates the frame of the orbit posteriorly. These animals have no os malæ. We can, however, easily distinguish two ossa nasi, two ossa maxillaria superiora, two ossa intermaxillaria, and some analogous to the palatine arches of birds, which are furnished with teeth, and which are articulated to the bone which supplies the place of the os quadratum, with respect to the lower jaw. Two particular bones unite these arches to the maxillaria superiora.

In those that have teeth, or poisonous hooks, as the viper, the rattlesnake, &c. there are besides two small peculiar bones, articulated and moveable, which support those teeth. They are situated upon the intermaxillary bones and the anterior extremity of the osseous branch, which joins the superior maxillary bone to the arch of the palate.

The face of the tortoise is circular before, and rounded on every side. It is composed of nearly the same bones as that of the crocodile. The intermaxillary bones are, at a very early period, consolidated with those of the upper jaw. The bones analogous to the os malæ are three in number, one articulates with the os temporum and with the two others; it is situated posteriorly, and forms the zygomatic arch. The other two portions are received on its anterior extremity; one extends upwards, and unites with the orbital angle of the os frontis; the other is directed

REPTILES.

downward, and articulates with the posterior and external process of the os maxillare superius.

The ossa palati are broad, and form the posterior arch of the nasal fossa.

The bones of the face of tortoises commonly cover each other at their edges, which are refined into thin laminae. It is therefore very difficult to distinguish the futures.

In the sea tortoises the temporal fossae, which are very deep, are covered by an osseous lamina, which forms a very solid arch above them.

The description of the jaws, and the temporal fossae, is given at the beginning of the account of the digestive organs.

Cavities of the Face.—1. *Nasal Cavity.* It is a broad space in the tortoises, occupying the whole thickness of the snout in front of the eyes, and very short from before backwards. Its front opening is large, and nearly square, with its plane but little inclined; surrounded by six bones. There are two round openings behind, corresponding nearly to the middle of the palate.

In the crocodile it is a long and narrow canal, extending from the end of the snout under the occiput: its bony opening, formed entirely in the two intermaxillary bones, is turned upwards.

Other lizards have the nasal apertures situated nearly as in birds: that is, the front or outer on the side of the snout, and the back or inner in the middle of the palate. They are still shorter in the frogs.

2. The orbit is never separated from the temporal fossa in reptiles by a partition, but merely by a bony branch; and even this is complete only in the lizards and tortoises, not in the frogs, salamanders, or serpents. The plane of its margin is lateral in the tortoises, serpents, and cameleon; it is more or less directed upwards in the crocodile, salamanders, and frogs. The figure varies from circular to triangular. The inferior surface or floor is never complete: either it is altogether deficient, or it is perforated by a very large aperture. The same remarks are applicable to the inter-orbital septum.

The zygomatic fossae are spoken of in the description of the jaws and their movements, under the division of *Organs of the Vital Functions.*

Foramina of the Face.—Where there is no distinction between the orbit and temporal fossa, the sphenomaxillary fissure is of course wanting. There are no internal orbital holes, as the relation between the orbits and nose is altogether different from what is observed in the mammalia.

The crocodile, frog, and salamander, possess a large foramen incisivum. The tortoise has two small ones: the structure of the lizards is not known.

There is no suborbital opening, reptiles having no lips to receive the artery and nerve, which it transmits in the mammalia.

The sphenopalatine canal appears as a simple hole in the os palati.

Motions of the Head.—The articulation of the head of reptiles is considerably behind, but the motions vary in different species.

In the crocodile there is only one condyle, situated at the under side of the foramen magnum: the atlas is formed of two portions; the posterior is shaped like the segment of a ring; the anterior, which is thicker, receives the condyle, and is articulated to the second vertebra: there are two lateral processes, long, flat, and turned backward, which supply the place of transverse processes.

The odontoid process of the second vertebra is short and thick; it is articulated within a cavity in the body of the

atlas. This second vertebra has transverse processes similar to those of the first.

All other lizards have nearly the same conformation; but the condyle seems divided in two by a longitudinal superficial furrow.

The tortoises have likewise only one condyle. In the land sort it is prolonged, and divided into two, as it is in the lizards. In the marine species it presents three articular faces, like a trefoil leaf. As this condyle penetrates deep into the correspondent cavity of the atlas, the lateral motion of the head is much confined. The other motions of the head of the tortoise are those of projection and retraction; they depend upon the flexion and extension of the cervical vertebrae.

The frog, the toad, and the salamander, have the head articulated by two condyles upon the first vertebra, which is almost immoveable.

Serpents have three surfaces, in the manner of a trefoil, close together, upon one condyle, beneath the occipital foramen. The head is not more moveable on the atlas, than the rest of the vertebrae are upon each other.

Bones of the Spine.—The number of vertebrae, and every other attribute of the spine, are more varied in this class of animals than in any other.

In the tortoises, seven vertebrae are assigned to the neck: the first is only a single tubercle, the annular portion of which is very distinct. The surface, by which it is articulated with the head, is formed of three planes; one anterior, and two lateral. The point in which they unite is the most prominent, and to this is attached a strong ligament. The surface which unites it to the next vertebra is a glenoid cavity; the second and the following vertebrae have a prominent longitudinal ridge upon the fore-part of their body. The articular processes descend below the body: there are no spinal processes, except one to the second vertebra, which points forward, and one to the third in the form of a simple tubercle. The two last vertebrae, at a certain age, become ankylosed. There are eight dorsal vertebrae; but they are all ankylosed, together with the ribs and the back-shell, in one immoveable piece. They have, therefore, neither processes nor articular surfaces: they are all narrower in the middle than at the ends. The lumbar and sacral vertebrae are likewise consolidated with the back-shell, but those of the tail are free and moveable. The condyle, which forms the body of these vertebrae at its articulation with the others, inclines backward, and not towards the head, as those of the neck do. There are likewise upon the fore-part of the body, at its base, two small tubercles; but all the processes of these vertebrae resemble those of the mammalia.

In the family of lizards, the crocodile has seven cervical vertebrae, distinct indeed, but so closely articulated as not to be moveable. The processes are so numerous, long, and close, that the animal cannot bend its neck, and the cervical column may, therefore, be regarded as a single piece. This corresponds with the reports of travellers, that the crocodile is unable to turn his head round. The anterior surface of the body is concave, and the posterior convex, throughout the vertebral column of the crocodile. The atlas is composed of six pieces, which appear to continue separate through life: the vertebra dentata has five only. The other cervical vertebrae have on each side two short transverse processes, which serve to support the small ribs or appendices, which limit the flexion of the neck. Each has two pedicles, attached to the two processes just mentioned: the appendix projects into a sharp process before and behind, which touch those of the contiguous vertebrae. The five

REPTILES.

five first dorsal vertebræ have a lateral tubercle for the head of the rib, and another on the transverse process for its tubercle: thus the rib is articulated only to one vertebra. But the first of these articular surfaces is wanting in the remaining ribs, while each of their transverse processes has two articular faces. The same number (seven) is found in most lizards, though the camoleon has only two. The sacral vertebræ are very few in every species, and none of them have a large os sacrum.

As frogs have no ribs, no distinction can be formed with respect to the three first orders of vertebræ in them. They have in general eight between the neck and the pelvis, all furnished with pretty long transverse processes. The last are the longest, and touch the ossa ilii. In the toads, the transverse processes are very large, and shaped like hatchet blades. The os sacrum consists of a single bone only: it is long, pointed, compressed, and has no coccyx. In the pipa, which has the transverse processes of the second and third vertebræ much longer than the others and almost like ribs, this bone is ossified with the last vertebræ.

The salamanders have fourteen vertebræ between the head and the sacrum; they have all nearly the same shape, except the first, which receives the head, and the last, which is articulated to the sacrum. The two extremes of the spine alone want the vestiges of the ribs, which consist of small oblong moveable bones, actually articulated to the transverse processes, which here take a posterior direction. The articular processes are large, and wedged together. The posterior rest upon the anterior, so as to impede the motion of the spine backward. The sacrum consists only of a single vertebra, but there are twenty-seven in the tail.

In serpents, the vertebræ alone constitute almost the whole skeleton. It appears in general, says Blumenbach, that the number of vertebræ, in red-blooded animals, is in an inverse proportion with the size and strength of their external organs of motion. Serpents, therefore, which entirely want these organs, have the most numerous vertebræ; sometimes more than three hundred. (Comp. Anat. p. 118.) In confirmation of this remark, we may observe how numerous the vertebræ are in the elongated fishes, as the eel, and in the whales, as the porpoise, (above one hundred in the former, and between sixty and seventy in the latter). Birds, whose wings give them such vast power of locomotion, have very few vertebræ, if we consider the ankylosed ones as forming a single piece; and the frog, with its immense hind extremities, has a very short spine, consisting of still fewer pieces than that of birds. The vertebræ of this order are nearly of the same form, from the head to the tail: the body, as well as the spinous, articular, and transverse processes, are easily distinguished. In certain kinds, for instance the boxæ, the spinous processes, which are continued throughout the whole length of the back, are separated from each other, and allow reciprocally a motion sufficiently conspicuous. Wherever this disposition of the spinous processes prevails, the body of the vertebræ, on the side next the belly, presents only an obscure projecting line. In other kinds of serpents, as for example the rattlesnake, the spinous processes are long, and so large as to touch each other. They have, for their basis, the articular processes, which lie on each other like tiles. In consequence of this structure, the motion of the spine towards the back is very circumscribed, but its motion towards the belly and sides much augmented. The bodies of the vertebræ play very easily in these directions upon one another, and are armed with a sharp spine tending towards the tail, which only obstructs their motion when it might produce a luxation. The first vertebræ differ from those of the rest of the body,

only in having the rudiments of the ribs much smaller: there is no neck in these animals. The vertebræ of the tail differ no farther than in having no ribs, and that their spines, both ventral and dorsal, are double, or form two ranges of tubercles. The articulation of the bodies of the vertebræ with each other is very remarkable: the anterior part of the body of the vertebra presents a smooth hemispherical tubercle, and the posterior part a corresponding cavity; so that each vertebra becomes connected to those next it by a sort of knee-joint. This mode of articulation fully explains the motion of reptiles, which is performed winding from side to side, and not up and down, as it is represented by painters.

Table of the Number of the Vertebræ in Reptiles.

I. Oviparous Quadrupeds.

Species.	Vertebræ of the Neck.	Vertebræ of the Back.	Vertebræ of the Loias.	Vertebræ of the Sacrum.	Vertebræ of the Tail.
Turtle - - -	7	11	0	3	20
Crocodile - - -	7	12	5	2	34
Tupinambis - - -	7	18	4	2	104
Iguana - - -	5	11	9	2	72
Camoleon - - -	2	17	3	1	69
Salamander - - -	1	12	1	1	26
Frog - - - - -	10 in all.				
Pipa or Surinam toad	8 in all.				

II. Serpents.

Species.	Vertebræ to which Ribs are joined.	Vertebræ of the Tail.
Viper (berus) - - - -	139	55
Spectacle snake (naia) -	192	63
Garter snake (natrix) - -	204	112
Amphisbæna - - - -	54	7
Boa (constrictor) - - -	252	52
Common snake - - - -	244	More than 60.
Rattlesnake - - - -	175	26
Slow worm (anguis fragilis)	32	17

Of the Ribs and Sternum.—The thorax of reptiles is very various in its structure. Frogs have a sternum, but no ribs; serpents have ribs, but no sternum; tortoises have the ribs ossified to the back-shell, and the sternum included in the breast-plate; the crocodile and lizard have perfect ribs, but their sternum is almost entirely cartilaginous. In the crocodile, the first portion of the sternum is ossified and elongated. It receives the two clavicles. The remaining part is entirely cartilaginous. It is united with the os pubis, and sends off eight cylindrical cartilages to the parietes of the abdomen. This structure, constituting a species of abdominal sternum, apparently for supporting the viscera, is quite peculiar to the crocodile. The ribs are twelve in number, the two first and two last of which are not attached to the sternum. The intermediate ribs have upon their posterior edges cartilages partly ossified, which supply the place of the angles of the ribs in birds. All the posterior ribs, beginning at the fifth, are only articulated to the transverse processes of the vertebræ, which are of great length. The five first articulate with the vertebræ at two points, one on

REPTILES.

its body, and the other on the transverse processes. The iguana and the tupinambis have only the upper part of the sternum ossified: it is broad, and receives six ribs and the clavicles; the other ribs are free. Theameleon possesses likewise the upper portion of the sternum; but almost all the ribs have cartilages, which extend to the middle line, and are there united to the opposite ones. Frogs, though they have no ribs, have nevertheless a very conspicuous sternum. It forms on the anterior part a cartilaginous appendix, furnished by a disk situated below the larynx. It next receives the clavicles, and then expanding, it terminates at last in another disk situated under the abdomen, and which affords an origin for muscles. There is a peculiar bony cyst of unknown use on the internal surface of the sternum, in the rana pipa.

The salamander has ribs, so short that they seem to be the transverse processes of the vertebræ; they have only one point of articulation, upon which they have but little motion. These rudiments of ribs are twelve in number on each side. This reptile has, properly speaking, no sternum, but its place is partly supplied by the bones of the shoulder, as we shall presently see.

The skeleton of the chelonian reptiles exhibits to us what appears on the first view as a completely anomalous organization. In the bony house which these animals carry about with them, there is such a deviation from the ordinary figure, connection, and position of the parts, composing the skeleton of other vertebral animals, that a hasty view would lead us to infer that the general model to which Nature in all her modifications of form and position ever adheres, has been completely lost sight of, and another substituted in its place. This inference would be altogether incorrect: a more accurate examination enables us to discover in the external bony shells of these singular creatures, all the osseous pieces which belong to the chest of a mammiferous animal or bird; so that no essential part is wanting in their thorax, and the singularity depends merely on the more or less complete ossification of the whole pectoral case, and the peculiar forms resulting from this circumstance. Thus, instead of the anomaly, which a hasty glance leads us to anticipate, we actually discover, on the contrary, a new proof of the constancy, with which an original model is retained throughout whole classes of animals, even under the widest differences of external form, as if Nature, having fixed on one general principle of organization, would not be at the trouble of inventing others, but rather chose, by the strangest modifications, to accommodate the organs to new situations and forms. It is a new illustration of that principle, in conformity to which the fin of a whale contains all the bones of an upper limb of a quadruped, the wing of the bat the regular digital phalanges, the fin of a penguin or seal the usual bones of the extremities of a bird or mammiferous animal, &c.

The bones of the chest in the tortoises form a more or less convex shield-like covering, which constitutes the upper surface of the animal; we call it the upper shell (*carapace*, *bouclier*, &c.); and a nearly flat portion adapted to its concavity below, constituting the inferior surface of the animal: this is the under shell (*plastron*).

The back shell is formed by the expansion of eight ribs or osseous staves, which arise from the joints of the vertebræ, and terminate in a border that furrounds the whole shell: these bones are united together by real sutures, situated transversely. Above, and all along the middle part of the shell, we observe a row of little osseous plates, almost square, intimately connected together, and to the plates formed by

the ribs, by synarthrosis, and equal in number to the vertebræ. These plates represent the rings and spinous processes of the vertebræ. The osseous margin is made up of a great number of pieces, (eleven on each side, and a single one in the middle, before and behind, therefore 24 in the whole,) folded together, which by their union form an edge or border with three surfaces, *viz.* the superior, which belongs to the back shell; the inferior, which is joined to the breast-plate by a very thick leather-like skin; and the internal, which presents a groove for the reception of the extremities of the ribs. These pieces, which Geoffroy compares to the sternal or cartilaginous portion of our ribs, are wanting in the soft tortoises, (*trionyx*, Geoff.); or at least remain constantly cartilaginous or membranous, so that the middle only of the upper shell is sustained by an osseous disk.

The turtles, and the soft tortoises, are the only genera in which the ribs, confounded in the upper shell or carapace, are nevertheless distinct, both by a prominence very apparent on the inside of the shell, and by a free unattached portion of their ends projecting beyond the edge of the shell. But the osseous disk, composed of articulated pieces, and already mentioned, extends round the ribs in the turtles, receiving their ends, but is wanting in the soft tortoises. Its solidity is increased in the former by the great plates which cover it, while it remains flexible in the latter, and is covered only by a species of epidermis.

The ossification of the intervals of the ribs, forming the carapace, is perfected gradually, and is not finished until long after that of the ribs themselves: it generally advances from the middle towards the edges. Thus, in a young turtle the ribs will be found separate from each other, towards their external extremities, for half their length; while in an adult individual of the same species, the anterior ribs are united throughout, while the intermediate ones are separated only through about one-sixth of their length.

The carapace is always oval and pointed behind in the turtles; elliptical and gibbous in the land tortoises; elliptical and flatter in the fresh-water tortoises. Its surface is rough in the soft tortoises; elevated into various prominences in the chelydes and the serpentine, and more or less smooth in the others.

The margin of the upper shell assumes a different appearance at its anterior part; it is there a square piece of bone, convex above, and concave below, which sustains a spine for the attachment of muscles. Its anterior edge has more the form of a crescent (*lunula*); there are also some little peculiar pieces above the tail.

The breast-plate of the tortoise is its sternum; and when deprived of the thick skin that covers it, exhibits, in some species, only one solid plate, formed of several pieces, united by synarthrosis: in others, this plate is perforated quite through, and formed of several bones, some of which are situated in the middle line between the anterior and posterior part, while others are placed laterally, and fastened together by the help of the former, which support them. For further information concerning the osseous fabric of the chest in these reptiles, two memoirs in the 14th vol. of the *Annales du Muséum* may be consulted; "Sur les Tortues molles, par Geoffroy St. Hilaire;" "Sur les ossemens Fossiles de Tortues, par Cuvier."

In the draco volans the ribs form the skeleton of the wings, or those expansions of the integuments between the front and back limbs, which are so called. The five posterior ribs are elongated and bent backwards for that purpose. Here progressive motion is performed by these ribs; but they are superadded for this purpose, and make no part of the organs of respiration. The animal cannot

REPTILES.

in truth be said to fly: its lateral membranes act like a parachute, and enable it to take long leaps.

The ribs are usually articulated to the vertebræ by means of a convex surface, which moves upon a slightly concave one formed in two of the vertebræ; so that the hollow receiving each rib is situated between two vertebræ of the back. But in the snake tribe the head of the rib has two slightly concave surfaces, which move upon a convex protuberance belonging to each vertebra; so that the rib rests on a single vertebra. The consequence of this peculiarity is, that the ribs do not interfere with the motions of the individual vertebræ, and thus that the latter are left free to execute those movements on each other, which take place so extensively in the progression of serpents. The articulations of the vertebræ to each other, and to the ribs, are represented of the natural size from the skeleton of a large boa, in the *Philos. Transf.* 1812, pt. 1. pl. 6.

We have already seen the ribs, instead of contributing to the business of respiration, employed for purposes of locomotion in the *draco volans*. They are still more extensively employed for the same purpose in the serpent tribe, in which they amount sometimes to 250 pairs, as observed by sir Everard Hume. These bones, in all snakes, are continued to the anus, while the lungs seldom occupy more than one-half the cavity covered by the ribs. The hind ribs can only be employed for the purpose of progressive motion, and thus correspond to the elongated ribs of the lateral membranes in the *draco volans*.

The ribs of a snake may be seen to move forwards successively when the animal is in motion, like the feet of a caterpillar, and the ends of these bones can be distinctly felt on the palm of the hand, as the animal passes over it.

At the termination of each rib is a small cartilage in shape corresponding to the rib, only tapering to the point. Those of the opposite ribs have no connection, and when the ribs are drawn outwards by the muscles, are separated to some distance, and rest through their whole length on the inner surface of the abdominal scuta, to which they are connected by a set of short muscles: they have also a connection with those of the neighbouring ribs by a set of short straight muscles.

When the snake is going to put itself in motion, the ribs of the opposite sides are drawn apart from each other, and the small cartilages at the ends of them are bent upon the upper surfaces of the abdominal scuta, upon which the ends of the ribs rest; and as the ribs move in pairs, the scutum under each pair is carried along with it. This scutum, by its posterior edge, lays hold of the ground, and becomes a fixed point, from whence to set out anew. This motion is beautifully seen, when a snake is climbing over an angle, to get upon a flat surface.

The coluber and boa, having larger abdominal scuta, which may be considered as hoofs or shoes, are the best fitted for this kind of progressive motion; there is, however, a similar structure of ribs and muscles in the *anguis* and *amphisbæna*. In the *anguis* the ribs are proportionally weaker, and as these have nothing to correspond to the scuta, this mode of progressive motion is probably less necessary to them. See "Observations intended to shew that the progressive Motion of Snakes is partly performed by means of the Ribs," by sir Everard Hume, *Philos. Transact.* 1812, pt. 1. pag. 183, with figures. We are also indebted to sir Everard Hume, in conjunction with Dr. Ruffel, for describing more particularly a fact noticed by Blumenbach, (*Comp. Anat.* p. 117.), viz. an adaptation of certain ribs in the cobra de capello (*coluber naia*, L.) to the accomplishment of a particular mechanism in that animal.

This serpent is called the hooded snake, from a power of expanding the skin of the neck, which is effected by the motions of the ribs. In other serpents, the ribs, from the first vertebra to those of the middle of the trunk, gradually increase in length; thence they gradually shorten or decline, to near the end of the tail, where they disappear, or are transformed into short eminences. In the naia, the cervical ribs gradually lengthen to the tenth or eleventh, after which they successively shorten to the twentieth. Again increasing in length, they are, at the middle of the trunk, nearly as long as the middle cervical ribs, and then declining as in other serpents, disappear on the tail.

The first twenty ribs, instead of bending equally with the others towards the belly, go out in a lateral direction, having only a slight curvature, and when depressed lie at the side of the spine upon one another. The first is shortest: they lengthen to the tenth, and are again shortened to the twentieth; so that, when they are extended, they represent an oval figure, of which the spine is the middle line or long axis. In the extended state of the ribs, the skin of the back is brought over them, forming the hood; and in their depressed state it recedes. From the rounded form of the hood, the skin has the appearance of being inflated; but the most careful examination did not discover any communication between the trachea or the lungs and the cellular membrane under the skin. See "Remarks on the voluntary Expansion of the Skin of the Neck in the Cobra de Capello," &c. by Pat. Ruffel, M.D. and Everard Hume, esq. *Philos. Transf.* 1804, pt. 2. pag. 346.

The existence of ribs has been denied in the firen laceratina, and proteus anguinus: they have in truth merely very insignificant rudiments of ribs, that might be easily overlooked. These have nothing to do with the respiration of the animals, indeed they are too small to answer any purpose. See the description of these animals at the end of the present article.

Such rudiments of ribs are said to exist in the genus *cæcilia*, among serpents.

Bones of the Shoulder.—In oviparous quadrupeds the glenoid cavity of the shoulder is partly composed of the scapula, and partly of the clavicle. The scapula, which is elongated, has no spine; it contracts and becomes thicker towards the neck. The clavicle is simple, short, and flat, and united to the sternum in the crocodile and lizards. It is broad, and almost square, in the iguana and camelion; in the tupa-nambis it is oval, and very large and long between the front and back, and has two un-ossified parts. The frog and toad have two clavicles to each shoulder, attached to the two extremities of the sternum. The scapula is bent, and composed of two articulated pieces, with the superior one inclined towards the spine. The same conformation obtains in the Surinam toad. The anterior clavicles appear to correspond to the os furciforme of birds. The clavicle, the sternum, and the first piece of the scapula, are ankylosed together. The salamanders have the shoulder formed in a most singular manner, the scapula, clavicle, and sternum, consist only of a single bone, which receives the head of the humerus. The shoulder is almost all cartilaginous, but the part answering to the scapula is more distinct than the rest. It inclines towards the spine, where it receives the muscles by which it is moved. The clavicular part is directed towards the head; that which supplies the place of the sternum turns towards the breast, but without uniting with the bone of the opposite side; the part on the right side slides over that on the left. This conformation allows a greater dilatation of the breast in respiration. The tortoise

REPTILES.

has also these three bones, which unite to form the glenoid cavity, and correspond with the scapula, fork, and clavicle. But as their respective disposition is very remarkable, it appears necessary to give a particular description of them. One of the bones extends from the base of the rudiment of the first rib, to which it is fixed by a ligament, as high as the humeral cavity, where it is intimately connected with the other two. The second bone may be considered as the continuation of the first, which it joins at the humeral cavity, of which it forms part. Its other extremity is attached to the breast-plate, and strong ligaments likewise unite the extremity to that of the posterior bone. These two bones, thus united, are slightly bent outwards, so as to leave between them and those of the opposite side, an oval space, through which the œsophagus, the trachea, and several muscles, pass. The first seems to correspond to the clavicle, and the second to the os furciforme. Finally, the third bone of the shoulder is situated below the abdominal and thoracic viscera, nearer the breast-plate. It is long, and extends from the humeral cavity, of which it forms the lower part, as far as the abdomen. It seems to supply the place of the scapula by the number of muscles inserted into it, but its situation is just the reverse of that bone. A very strong ligament unites this bone to the second.

Bone of the Arm.—The humerus of the tortoise has a very remarkable shape. As in birds it is articulated at once to the scapula, clavicle, and os furciforme, by a large oval head, the greatest diameter of which lies in the direction of the flatness of the bone. A considerable eminence rises above this large head, which, by its curvature and its uses, has some relation to the olecranon, a process which, in this animal, the bone of the fore-arm wants. Below the head there is another eminence, less projecting, but more rough, which likewise serves as a point of insertion to some muscles, and supplies the place of the little tuberosity. The rest of the body of the bone is flattened and narrow towards the middle. In the crocodile, the humerus is round, but a little bent like an S in its whole length. At the extremity that joins the scapula, it resembles the tibia; its head, instead of being round, is flat; and its tuberosity, which is single, is anteriorly in the form of a ridge, and somewhat inclined inwards. In the other lizards, and in frogs, the humerus exhibits nothing peculiar. Serpents having no limbs, have consequently no humerus.

Bones of the Fore-arm.—The humerus of the crocodile terminates in two round tubercles. The hollow head of the radius turns upon the external one. Between them the round head of the ulna is situated, but it has neither olecranon nor sigmoid cavity. In the upper part it is the largest of the two bones, but the smallest below. There is nearly the same conformation in the camelion, but the bones are more elongated, and the inferior head of the radius is less than that of the ulna. In the frog the single bone of the fore-arm is articulated by a concave head, with a large round tuberosity on the base of the humerus, between its two condyles. On each side, where the lower part of this bone becomes larger, we observe a furrow, which is the only vestige of a distinction into two bones. Troja has pointed out a singularity in the structure of the bone of the fore-arm and of the leg in frogs and toads. These bones consist of a single piece, which is solid in the middle, but divided at either extremity into two conical portions, having manifest medullary cavities. See Memoria sopra la struttura singolare della tibia e del cubito nelle Rane e nei Rospi, in his Spierenze intorno alla Rigenerazione delle Ossa. Nap. 1779, p. 250, t. 7, 8.

The two bones of the fore-arm of salamanders are situated

one above the other. The ulna, which is the lowest, and somewhat longest of the two, has no olecranon; but there is a sort of rotula in the tendon of the extensor muscles. The ulnar extremity of the humerus is much enlarged. The articulate surface which terminates it is convex, and permits the radius and ulna to turn together in every direction. The two bones of the fore-arm in the turtle are always in a forced state of pronation. The radius, which is much longer than the ulna, and fixed to it by a cartilaginous substance, is the lowest, and extends even under the carpus. These two bones much resemble each other in the humeral extremity, being formed by a single concave surface received upon a correspondent pulley of the humerus. Their articulation is such that it allows them to move together laterally, and a little upward and downward in the action of swimming.

Bones of the Hand.—The frog, the toad, the salamander, have three ranges in the carpus. The first consists of two bones, one radial and one ulnar; the second consists of three bones, the largest of which bears the rudiment of a thumb with two joints; the third range has likewise three bones. The second fingers proceed from the first of these bones; the fourth finger is articulated with the second bone; the middle finger articulates with both bones; the little finger joins the third bone. The first range touches the third inferiorly, because the second is cuneiform. There is no bone without the range. In the mud tortoise, the first range is a single bone, which separates the radius from the ulna: the second range consists of two bones, and a small one out of the row, situated on the ulnar edge: the third range consists of five bones, one for each bone of the metacarpus. The sea tortoise has three bones in the first range, the ulnar bone being the longest. The two anterior bones do not advance much farther. The third range consists only of three bones for those of the metacarpus, and one small bone out of the row, situated upon the radial side.

In the crocodile, the first range consists of two long parallel bones. It has besides two little external bones without the range on the radial side. The number of the phalanges varies in these animals. The crocodile has the hand rounded. It has two phalanges to the thumb, three to the second finger, four to the middle and fourth fingers, and only three to the little fingers.

The camelion has three fingers on one side, and two on the other, which form, with the three opposite to them, a kind of forceps. The number of the phalanges is the same as in the crocodile, with the exception of the little finger, which has four. In the salamander the little finger is obliterated, and the thumb has only two phalanges.

The frog has only one phalanx to the thumb. The two following fingers have only two phalanges. The other two fingers have three.

The hand of the sea tortoise is long, and compressed in the form of a fan; there are two phalanges to the thumb, three to the three succeeding toes, and two only to the last. A similar conformation is observable in the mud tortoise; with this exception, that its hand is rounded.

Bones of the Pelvis.—In the turtle, that part of the os innominatum which corresponds to the pubis, is the most considerable. It proceeds from the cotyloid cavity by a thick portion, which comes forwards and widens into a thin flat lamina, divided into two parts; one is turned towards the middle line, by which the two corresponding bones are united; the other is free, and is directed to the external side. The portion which corresponds with the ilium is short, narrow, and thick; it rests on the shell, and is joined to the sacrum; finally, the portion which is analogous to

REPTILES.

the ischium is turned backward and downward, and forms the real osseous circle of the pelvis. This conformation is so singular, that the parts of the pelvis of the turtle, when the whole is viewed out of its natural position, may very easily be mistaken for one another; for the pubis resembles the ilium, the ischium the pubis, and the ilium the ischium. There is, besides, another very remarkable peculiarity in the pelvis of tortoises; the ilium, and consequently the whole mass of the pelvis with which that bone is united, is moveable on the vertebral column.

In the crocodile, and in the tupinambis, the disposition of the pelvis has a great resemblance to that of the tortoise. In the crocodile the pubis receives the ventral ribs. In the camelion and the iguana it is narrow, and the bones of the ischium form, by this union, a projecting crest. In the frog, and in the Surinam and common toads, the ossa ilii are much elongated; the pubis and the ischium are short, and united in a single solid piece, the symphysis of which forms a crest, more or less round. In the salamander, the conformation is precisely the same. The ossa ilii are narrow, and almost cylindrical; and the ossa pubis completely united with the ischium, form only a large bony plate without any hole.

Thigh-Bone.—The femur of oviparous quadrupeds resembles that of other animals; it has, however, a double curvature, more or less evident. In front it presents a convexity towards the tibial extremity, and a concavity near the pelvis. In the tortoise the trochanters are well defined, but they are not to be found in the lizards and frogs. The figure of the femur is in general round, except in the Surinam toad, in which it is very flat.

Bones of the Leg.—Oviparous quadrupeds have the tibia and fibula distinct and separated from each other throughout their whole length. These two bones are nearly of the same magnitude in the tortoises and lizards. The frog has but one bone, but a furrow seems to indicate the union of the tibia and fibula. In these animals the tibia and fibula are, for the most part, directly articulated to the thigh-bone.

Bones of the Ankle.—The astragalus is articulated to the tibia, and the os calcis to the fibula in all reptiles. The tarsus of the crocodile has five bones, viz. an astragalus, an os calcis, two cuneiformia, answering to the two middle metatarsal bones, and one out of the range, which answers to the external metatarsal bone. There are four metatarsal bones. The bone situated without the range serves to support the little toe in the mud tortoise. In the sea tortoise it is very flat. The os calcis and astragalus are very small. In frogs, the astragalus and os calcis are very long, and might at first sight be taken for the tibia and fibula, if they did not form the third joint of the posterior extremity. There are on the fore part, four little cuneiform, five metatarsal bones, and one in the form of a hook, which is very minute. These are similar in the Surinam and common toad.

Bones of the Toes.—The number of the toes varies much in reptiles; as may be seen from the following table.

Number of the phalanges of the toes of reptiles, exclusive of the metatarsal bones, beginning at the pollex, or internal toe.

The saurians present us with arrangements in their extremities, not met with in any of the mammalia. We have species possessing only fore-limbs, or only hind-limbs; others with four limbs, and one toe only on each; and other unusual combinations in the number of toes on the fore and hind-limbs. These circumstances are noticed in those lizards which approach to the form of serpents, and whose small imperfect limbs seem more like rudiments than complete members, serving as intermediate links between the saurian and ophidian orders. See Lacépède in the Ann. du Muséum, ii. p. 351, with figures of a lézard monodactyle, and tetradactyle; and Daudin in his Hist. Nat. des Reptiles, vol. iv. in the history of the genera Seps and Chalcide. We know nothing, however, about the osteology of these—we might almost say—ridiculous limbs, they are so obviously inadequate to the purpose of locomotion.

Of the Muscles.

Muscles of the Spine.—There are few spinal muscles in frogs. The muscle which is analogous to the ischio-coccygeus is large and thin, and occupies all the space comprised between the long bone of the coccyx and the ilia. Its fibres are oblique, and it serves to draw the coccyx into the direction of the spine. That which is analogous to the lumbo-costalis, arises above the last by a sort of point attached to the coccyx. It extends quite to the head, into which it is inserted, and detaches fibres in its progress to each of the transverse processes, which form a kind of intersection upon its surface. The obliquus superior arises from the head at the margin of the foramen magnum, and is inserted into the transverse processes of the first dorsal vertebra. There is only one small rectus anterior, it arises from the base of the cranium, below the foramen magnum, and is inserted into the first of the transverse processes. The inter-transversales are like the human. The spinal muscles of the salamander much resemble those of the frog; those of the tail are very similar to the muscles of fishes. The spine of the tortoise has no motion except in the parts belonging to the neck and tail. Those of the back and loins, which are ossified together, have no muscles. The muscles of the neck are very different from those of man. The motions they produce are those of elongation, by which the head is protruded from the shell; and those of retraction, by which it is withdrawn, the neck being bent in the form of a Z. The first of the muscles proper to the neck is attached to the under part of the anterior lateral border of the back-shell, and into the transverse process of the first vertebra; it raises the neck and draws it back. Another proceeds from the anterior and middle part of the shell: it is inserted by four fleshy lips, which are separate throughout a considerable portion of their extent, into the articular processes of the third, fourth, fifth, and sixth vertebrae of the neck. It draws the neck back when the head is much extended, and pushes it out when it is retracted. A muscle also arises from the articular processes of the third, fourth, and fifth vertebrae of the neck, by three fleshy portions that afterwards unite, and terminate in two tendons; one of which is inserted into the transverse process of the first, and the other into the spinous process of the second vertebra. This muscle bends the neck upon itself, making it describe a curve, which is convex downwards; this motion brings the head under the shell. A muscle analogous to the longus colli arises from the under part of the body of the second dorsal vertebra, beneath the shell; it ascends along the neck, and furnishes aponeurotic slips to all the transverse processes,

REPTILES.

as far as the second vertebra, where it is inserted. This also is one of the retractors of the head. There are very distinct inter-articulares, which by their action elevate each of the vertebræ, and consequently extend the neck. The transverso-spinalis is situated on the posterior part of the neck: it arises from all the superior transverse processes, and is inserted into all the spinous processes as far as the sixth. Finally, a short muscle proceeds from the upper part of the first dorsal vertebra below the shell, and is inserted into the articular processes of the sixth and seventh cervical vertebræ. This muscle is peculiar to the tortoise, and begins the extension of the neck when the head is concealed within the shell.

Muscles of the Ribs, Abdomen, &c.—In the frog, which wants ribs, and the tortoise, where they are immoveable, the muscles which usually have their insertions in them, are in those animals extended to other parts. Thus in the tortoise, whose breast-plate occupies the place of the abdominal muscles, they are inserted into the pelvis, which they move. With respect to those animals, one very remarkable observation may, in general, be made. It appears that the very singular shape of the muscles and bones depend upon each other. Indeed, as the muscles are not placed upon the bones, they have not, if we may be allowed the expression, fashioned them; and the want of motion in the bones, which has given an unnatural figure to the trunk, has also given to the muscles other forms and other uses. The abdominal muscles of the frog present nothing peculiar, except that the skin does not adhere to their surfaces, and that instead of being inserted into the ribs, they are fastened to the sternum by a strong aponeurosis. The same observations may be made with respect to the salamanders.

We have described, in the osteology, the adaptation of the ribs of serpents to the purpose of progressive motion; and now proceed to point out the muscles by which they are moved forwards or backwards, and connected to the abdominal scuta. The ribs are brought forwards by five sets of muscles placed on the outside of the chest, and passing obliquely from above, downwards, outwards, and backwards. 1. One from the transverse process of each vertebra to the rib behind it. 2. The next set arises from the ribs, at a short distance from the spine, passes over two ribs, sending a slip to each, and ends in the third. The third arises from the posterior edge of each rib, passes over two ribs, and is inserted into the third rib behind it. The fourth set passes over one rib and is inserted in the second. The fifth goes from rib to rib.

The muscles carrying the ribs backwards are found on the inside of the chest, and slant from the spine forwards and outwards. A strong set arises from the anterior surface of the vertebra, goes over four ribs, to be inserted into the fifth about its middle. The serrated portions of a strong flat muscle, forming the muscular covering of the abdomen, arise from this part (the middle of the internal surface) of each rib. The right and left muscles unite in a beautiful middle tendon. Thus it is obvious, that the inferior half of each rib (below the origin of the serrated portion just described) is external to the abdominal muscle, and consequently free for the purpose of progressive motion.

The ends of the ribs are connected to the abdominal scuta by a set of short muscles: they are also connected together by short and straight muscles. Another set goes from the heads of the ribs obliquely backwards to be fixed in the skin at the edge of each scutum. See sir E. Hume's paper quoted in the osteology; and particularly

plates 4 and 5 from Mr. Clift's drawings, in which the parts are represented.

There is a complicated muscular apparatus for extending and retracting the ribs, and carrying the skin forwards and backwards in the cobra de capello. The ribs are raised or carried forwards by four sets of muscles, all arising from and inserted in these bones, and directed obliquely from above, downwards and outwards.

The skin of the back is brought forwards on the neck by a large set of very long muscles, arising successively from each of the first twenty ribs, by a tendon, which soon becomes fleshy. The longest is about two inches. They go backwards to be inserted into the skin; which they can bring forwards to a great extent when the ribs have been first extended.

The muscles which carry the ribs back again lie on the inside of the chest under the spine. One set goes from the vertebræ of the neck to the lower edges of the ribs: but they pass obliquely upwards and outwards over three ribs, to be inserted into the fourth, thus acquiring a length of fibre, by which the range of motion produced is much increased. The second set goes from the ends of the ribs forwards to the skin, which they will draw back. The third set from the root of one scutum to the scutum immediately above it, so as to bring it down upon the other. Sir E. Hume's and Dr. Ruffel's paper, and particularly the engravings from Mr. Clift's drawings. Phil. Transf. 1804, pt. 2.

Muscles of the Head.—The muscles of the head of the tortoise cannot be described under names similar to those of mammiferous animals and birds, because the shell affords insertion to the greater number of them. We will, therefore, only distinguish them by the points of attachment. Thus, on viewing the back part of the neck, we remark, 1st, at the anterior part of the back-shell, near the angle of the lunula, a broad muscle, which extends to the lateral and posterior parts of the head, into which it is inserted. It pulls the head backward. 2. Beneath, and from the middle of the anterior lunula of the back-shell, there arises another muscle, which is thin and round, and which, in separating from that of the opposite side, forms an angle like the letter V: it is inserted on the outside of the preceding muscle, and has the same use. 3. A muscle analogous to the splenius capitis rises from the spinous processes of the fourth and fifth cervical vertebræ, by distinct slips, and is inserted into the occipital arch. Its use is to raise the head. 4. A muscle analogous to the rectus major anticus rises from the inferior tubercles of the four vertebræ next to the atlas, and is inserted, fleshy and thick, into the depression of the cuneiform process below the condyle. 5. The trachelo-mastoides rises from the inferior tubercles of the second and third cervical vertebræ, by two thin aponeurotic tendons; it is inserted, by a very thick and entirely fleshy portion, into the protuberance that answers to the mastoid process. Its use is to bend the head laterally. 6. Lastly, at the superior part of the cervical spine there is a short muscle, which proceeds from the inferior part of the foramen, formed by the temporal fossa, and is inserted into the spinous process of the first, second, and third vertebræ of the neck. On viewing the neck in front, we observe the muscle analogous to the itero-cleido-mastoides attached to the strong aponeuroses that surround the humerus at its articulation with the scapula. The lower part of it, for one-third of its length, can only be seen, the remainder being concealed by a muscle composed of transverse fibres, which supplies the place of the mylo-hyoideus, and platysma-myoides. It is inserted into a process corresponding to the mastoid. Its use is to draw

REPTILES.

draw the head inwardly, and to produce a small elevation of the shoulders. The longus capitis arises from the third vertebra of the back, and is inserted by a slender tendon into the cuneiform process of the occiput. The frogs have very few of the muscles of the head: most of those which are inserted in it are employed in moving the superior extremities, or are proper to the vertebral column. The muscle analogous to the obliquus superior arises from the first transverse processes of the spine, and is inserted into the superior part of the occiput: its direction is oblique from without inwards. That which is analogous to the rectus capitis anticus minor, arises from the transverse process of the first vertebra, and is inserted into the basis of the cranium below the foramen magnum. These are the only two muscles proper to the head in frogs: they are similar in the land salamander.

Muscles of the Shoulders.—In the frog (which has no ribs) the ferratus major has an extraordinary shape, which appears to be occasioned in part by the want of the cervical vertebra: it forms three distinct muscles. The first arises from the occiput, near to the foramen magnum. It divides into two bellies, which are inserted into the superior spinal angle of the scapula: one on the internal, and the other on the external side. The second proceeds from the second transverse process, and passes under the dorsal portion of the scapula, towards its spinal edge. The third proceeds from the third transverse process, and passes underneath the preceding, keeping still nearer to the edge. There is besides another muscle proper to the scapula, situated upon its internal surface, between the two constituent parts, which make it appear broken. It appears to draw these two parts closer together, and by its contraction renders the angle they form with each other more acute. There is no muscle analogous to the pectoralis minor. The place of the levator, or angularis scapulae, is supplied by a very considerable muscle which rises from the base of the occiput; it becomes perceptibly smaller as it approaches the shoulders, and is inserted into the posterior edge of the cartilaginous part of the scapula. The omo-hyoideus is long and thin; it comes from the great inferior horn of the os hyoides, and is inserted under the neck of the scapula. The trapezius is wanting. The muscle analogous to the rhomboides is very thin. It arises from the dorsal processes, and is inserted into the spinal edge of the scapula. There is no subclavius muscle. The sterno-mastoideus has only one belly, which extends obliquely from the posterior part of the head, behind the ears, to the neck of the osseous part of the scapula. Its action is evidently that of pulling the shoulder towards the head, and raising it up. We shall describe the muscles of the tortoise separately, as they differ considerably from those of other red-blooded animals. They are only three in number. One of them, though very unlike the trapezius, is similar in its use; it rises from the lower surface of the back-shell among the ribs, from the second to the fifth. It is very thin, and passes to the external margin of the third bone of the shoulder, which seems to correspond with the scapula. A muscle analogous to the levator scapulae, is inserted into the curve formed by the joint of the two first bones of the shoulder. It arises by seven fleshy heads from the transverse processes of the seven vertebrae of the neck. Another little long muscle arises from the inner surface of the back-shell near the sternal extremity of the first rib, and is inserted into the dorsal extremity of the first bone of the shoulder. It is perhaps analogous to the costo-clavius.

Muscles of the Arm.—The pectoralis major of the frog is composed of two portions, placed one above the other. They produce two tendons which are inserted on each side

of the humeral groove. The latissimus dorsi arises from the inferior part of the back, where it is thin. It becomes thicker, and is attached to the broad part of the scapula, which it entirely covers. It is inserted, by a strong tendon, into the internal surface of the humerus, above one-third of its length from its superior end. In the frog there is neither the supra nor the infra-spinatus. The subscapularis or coracobrachialis, (for the muscle of which we now speak supplies the place of both,) arises from the internal surface of the scapula, at its junction with the clavicle, and is inserted into the interior part of the humerus about one-third from the head. The deltoid is formed of three portions. The first, which is the longest, and very slender, proceeds from the anterior part of the sternum. The second arises from the union of the clavicle with the scapula, at the internal surface, runs over the bone above the joint, then sends a thin tendon to the first in its passage, and is partly inserted in the linea aspera, and partly in the inferior portion of the humerus. The third is distinct; it rises partly from both the scapula and clavicle, and is inserted into the scapular extremity of the humerus. The teres major and teres minor are wanting. Besides these muscles, in which we discover an analogy to those of mammiferous animals, there is one which arises from the second transverse branch of the sternum, and is inserted into the inner edge of the groove of the humerus by a broad tendon. It may be regarded as an assistant to the pectoralis major. This conformation appears to prevail in the salamander.

If the tortoise has fewer muscles proper to the shoulder than common, it has an extraordinary number inserted into the humerus. That which corresponds to the pectoralis major is composed of five portions. Two are superficial; one arises from the edge of the anterior part of the breast-plate, and proceeds to its insertion in the lesser tubercle of the humerus. The other is much more extensive: it rises from a great part of the internal surface of the breast-plate, and is also inserted by a flat tendon in the lesser tubercle of the humerus: but it is prolonged by a fan-like aponeurosis, which extends over the inferior surface of the arm, and even of the fore-arm. One of the three deeper portions of the pectoralis major arises from the greater part of the second bone of the shoulder, and is inserted into the humerus, below its scapular articulation; another arises from the expansion of the interosseous ligament, which unites the second bone of the shoulder to the third, and proceeds to join its tendon intimately with that of the preceding portion. Lastly, the third, which is the most deep-seated of all, arises from the superior surface of the third bone of the shoulder, or that which is next the back-shell. Its tendon is conjoined with those of the preceding. The muscle analogous to the deltoides is also composed of two portions; one arises from a ridge on the anterior part of the breast-plate; the other, which is its accessory, is placed more deeply, and united to its corresponding muscle. They are inserted by one common tendon into the lesser tubercle of the humerus, which they draw towards the neck in the action of swimming. There is another muscle much deeper seated, which seems likewise an assistant to the deltoides. It rises from the dorsal extremity, and all the internal edge of that bone of the shoulder which corresponds with the clavicle, and proceeds to be inserted into the humerus below the lesser tuberosity. On the internal surface of the humerus, we find a muscle rising from the loose extremity of the sternal face of the third bone of the shoulder: it is inserted in the humerus, about one-third from its lower end, by a thin tendon. It bears some relation to the sterno-radialis of the frog, and performs the same office.

REPTILES.

The levator brachii is a very thick muscle, which arises from the third bone of the shoulder, the exterior edge of which it surrounds, and is inserted into the process of the humerus resembling the olecranon, which it pulls upward and outward. A muscle analogous to the teres major arises from the neck of the third bone of the shoulder, externally, and is inserted into the humerus between the two tuberosities. It pulls the humerus backward. Another muscle, which seems a substitute for the latissimus dorsi, rises from the interior part of the back-shell, to which it is attached obliquely, to the interval between the two first ribs. It is inserted into the body of the humerus behind the greater tubercle, by a flat tendon. It pulls the humerus towards the upper shell, when the animal stands upon all its four feet. A muscle, the use of which seems the same as that of the levator brachii, rises from the whole internal surface of that bone of the shoulder which answers to the clavicle, and is inserted into the whole length of the olecranon process, or great tuberosity of the humerus. It is very fleshy, and appears to be formed of two portions. Finally, the muscle analogous to the scapulo-radialis, or biceps flexor cubiti, arises from the anterior border of the humeral cavity, and is inserted into the external and superior surfaces of the humerus by a final tendon, which reaches as far as the base of the radius. It extends the member, and brings it toward the head.

Muscles of the Fore-arm.—The frog has, properly speaking, no biceps; its place is supplied by another, and much stronger muscle, situated on the breast, under the pectoralis major, with which it has the same insertions. At the articulation of the humerus it sends out a strong tendon, which passes along the groove of the humerus, and through a tendinous ring, formed by the two parts of the pectoralis major, under the deltoïdes. It is inserted into the humeral extremity of the radius, and may be named sterno-radialis. There is no brachialis internus. The triceps is composed of three parts, nearly as in man, but they are proportionally larger. There is but one supinator, which arises from the external condyle, and is inserted into the carpus. There is also but one pronator, which rises from the internal condyle, and is inserted into the carpus. In the turtle, these muscles are almost entirely aponeurotic, and produce but very little motion, the place of the member being supplied by a fin, as in the cetacea. In general, the muscles of the humerus produce the motions of the fore-arm.

Muscles of the Hand and Fingers.—In the sea tortoises, which have the carpus compressed and fitted for swimming, the muscles are only simple bands of aponeurotic fibres, which strengthen the several articulations. The muscles of the hand of the frog and salamander are very similar to those of man. Those of the thumb are wanting, except the extensor, which comes from the external condyle, and is inserted into the last phalanges. The other muscles vary very little.

Muscles of the Pelvis.—In the tortoise, the muscle analogous to the quadratus lumborum expands under the back-shell, between the last anterior ribs; it arises from the ilium, towards the articulation of that bone with the os sacrum, which in this animal is moveable. This mobility of the pelvis is assisted by a muscle analogous to the rectus abdominis, which, as we have observed, instead of extending under the belly, is attached under the posterior extremity of the breast-plate by two fleshy portions, the one anterior, the other posterior, which are both inserted in the anterior margin of the external branch of the pubis. There is no psoas parvus in frogs. The quadratus lumborum extends from the long transverse process of the third

vertebra, to the origin of the long bone of the pelvis, which is analogous to the ilium. It is inserted in this bone, which it raises towards the head; their ilium being moveable, like that of the tortoise.

Muscles of the Thigh.—In the frog there is only one glutæus, which is in the place of the medius. It arises from the elongation which supplies the place of the os ilium, and is inserted below the head of the femur. The pyriformis comes straight from the point of the coccyx, and is inserted about one-third from the top of the os femoris. The gemini and the obturator internus are wanting. The quadratus femoris is long. It arises from the posterior symphysis of the ischium, and is inserted into the inner side of the thigh-bone, about one-third from the head. They have neither the psoas magnus nor parvus. The iliacus is proportionally elongated. The pectineus descends to the middle of the thigh-bone. The three adductors have the same origins and insertions as in man. The obturator externus is to be found, though there is no foramen ovale. It arises from the symphysis pubis, and its fibres are attached to the capsular ligament. In the tortoise, the muscles of the thigh produce motions proper to swimming; that is to say, the abduction, the adduction, depression, and elevation of the thigh. The muscle analogous to the adductor longus arises from the symphysis pubis, and is inserted into the internal part of the thigh-bone, about one-third from its tibial extremity. Another muscle, which cannot be easily compared to any in man, arises from the interior of the sacrum, and is inserted into the little trochanters. It is another adductor femoris. A muscle, composed of different radiated fasciculi, arises from the broad inferior surface of the os pubis, and forms a thick tendon inserted into the little trochanter. It occupies the place, and answers the purposes, of the psoas and iliacus. That which is analogous to the adductor brevis arises from the symphysis of the bones of the ischium, and the interosseous ligament of the pubis. It is inserted into the os femoris, below the little trochanter. The muscle answering to the glutæus maximus arises from the spine, opposite to the last rib, and is inserted into the thigh-bone, below the great trochanter. The muscles analogous to the glutæus medius and minimus can hardly be distinguished from each other. They rise from the internal surface of the os pubis, and are inserted into the great trochanter. That which resembles the obturator internus arises from the internal surface of the ilium, and the superior edge of the cotyloid cavity, and is inserted into the great trochanter.

Muscles of the Leg.—The frog has the thighs round, like those of a man, and the muscles of the leg are very conspicuous. The triceps femoris is formed only of two very distinct portions. The vastus externus and cruralis are manifestly but one. There is no rectus anterior. The biceps flexor cruris has only one belly. It arises from the posterior and internal part of the ilium, and is inserted into the exterior and anterior surface of the tibia, for there is no fibula. The semi-membranosus is like the human; but the semi-tendinosus is composed of two bellies, one of which rises from the symphysis pubis, and the other from that of the ischium. The sartorius is situated exactly in the front of the thigh, without any obliquity. There is nothing remarkable in the gracilis. There is no distinct popliteus. Some differences occur in the muscles of the leg of the tortoise. These have a relation to the faculty of swimming, for which its extremities are fitted. The muscle which takes the place of the semi-membranosus arises from the interosseous ligament of the pelvis, and proceeds to form a strong aponeurosis at the inferior part of the leg. That which corresponds to the semi-tendinosus arises also from the interosseous liga-

ment;

REPTILES.

ment; it passes under the ham, and is inserted into the tibia, which it bends. That which is analogous to the sartorius arises from the os pubis, near the interosseous ligament, and passes over the knee, to be inserted into the tibia, which it extends. A muscle composed of two fleshy portions, both of which arise from the lateral parts of the sacrum, is inserted below the head of the tibia, and bends the leg. In its action, it much resembles the biceps, from which, however, it differs with respect to its attachments. Another muscle, resembling the fascia lata, and very thin in its fleshy part, arises from the sides of the coccyx. It passes under the skin of the fin, to its insertion, almost opposite to the heel. It bends the leg upon the thigh, and extends the foot upon the leg. The muscle analogous to the biceps arises from the sacrum and ilium. It goes to the external surface of the leg, where it is inserted into the fibula. The extensor of the leg presents nothing particular. The muscle analogous to the rectus anterior arises from the internal surface of the pubis, and joins the common tendons of the extensors.

Muscles of the Ankle.—In the frog, the gastrocnemius has only one belly; it has, however, a small tendon, by which it is inserted into the outward side of the head of the tibia. Its tendon runs under the heel, and there sliding over a sesamoid bone, expands itself under the foot, to form the plantar fascia. There is neither soleus nor plantaris. The tibialis anticus rises by a strong tendon from the lower part of the os femoris. About the middle of the tibia it divides into two bellies, one internal, the other external. The tendon of the first is inserted into the tibial base of the long bone of the tarsus, and that of the second into the same bone, a little more outwardly. An assistant to this muscle arises from the middle and anterior part of the tibia, and proceeds to the internal side of the base of the long bone of the tarsus. The tibialis posticus resembles the human, but it is only inserted into one bone of the tarsus, viz. that which is long, and situated at the inner side. There is but one muscle, to which the term peroneus can apply. It arises by a slender tendon, from the external condyle of the thigh, and is inserted into the base of the tibia, on the outside, by two tendinous portions, one of which extends to the bone of the tarsus. It extends the leg with respect to the thigh, or, more properly, the thigh with respect to the leg. Besides these muscles, which extend from the leg to the foot, there is another which arises from the metatarsal extremity of the tibia, at its internal edge, passes between the two bellies of the tibialis anticus, and proceeds very obliquely to its insertion, at the digital extremity of the long bone of the tarsus, on its inner side. In the sea tortoise, the muscles of the feet are supplied by aponeurotic fibres, somewhat fleshy, which serve only to strengthen the articulations, and keep the fins properly extended.

Muscles of the Toes.—There is no extensor longus digitorum in the frog; neither is there any flexor proprius pollicis. The extensor brevis digitorum is very distinct, it arises from the whole length of the long external bone of the tarsus, and extends obliquely to all the four toes, the last excepted. It is inserted into the last phalanges. There are superior and inferior interosseous muscles, which are very apparent, to the number of ten. Their direction is very oblique. The flexor communis digitorum is situated under the long bone of the tarsus, on the inner side, and is covered by the aponeurosis of the gastrocnemius. When it reaches the little bones of the tarsus it divides into five tendons, which receive, at their inner side, assistant fleshy fibres, apparently proceeding from a muscle situated below the long bone of the tarsus, on the inner side. It may per-

haps represent the flexor longus. In the sea tortoise all these muscles have their places supplied by bundles of aponeurotic fibres.

On the Support of the Body, and its Motions in Progression.—Standing is an attitude common to all animals, but the circumstances attending it differ very considerably. In most of the oviparous quadrupeds, the knees and elbows are directed outwards as they stand, and even during their various progressive motions. The posterior members, articulated more in proportion at the sides of the body, are so bent, that the belly descends to the ground, and moves along it.

Turtles rest on their plastron, and on their four flattened, elongated, and fin-like members. They may be compared to seals in their mode of executing movements. They employ their members, either in swimming, or in walking on the sea-shore, or in digging holes in the sand to receive their eggs.

In tortoises, standing is nearly the same as most in other oviparous quadrupeds; and the direction of their body is horizontal. Batracians, and frogs in particular, generally have their body, when at rest, in an oblique elevation; the arms sustaining the front part, while the back remains on the ground. The formation of the posterior limbs does not render them adapted to raise the body in a vertical direction, but merely to push it forwards.

Serpents, in a state of repose, coil up their body in several circles, either rising one above the other, or arranged one within the other; and the head is elevated above this coil. Those which inhabit trees are twined round the branches. The chalcides and biped lizards may be compared to serpents when at rest, for they are coiled up, and their limbs serve merely to prevent the body from rolling.

Walking exhibits different modifications, according to the number and form of the limbs, and the relative size of the fore and hind-feet. Where they are of equal length, the animals move with great velocity: hence the names of certain species, as *lacerta agilis* and *velox*. When, however, the limbs are too small and weak for the body, the movements are slower, as in the crocodile, the chalcides, and the toad.

The feet of the cameleon, and its prehensile tail, make it a better climber than most reptiles.

The limbs being all of nearly equal length in the sciaks, they cannot leap well: while the iguanas and tupinambes exhibit considerable agility. The frogs are the great jumpers, from the great length and strength of the hind limbs. But they can hardly walk; moving the front legs only with facility, and being obliged almost to drag the hind ones after them.

Serpents can leap or project their bodies by the sudden extension of several articulations: they form several curves with their body, and then suddenly straighten them, either in whole or in part, according to the leap which they may wish to make.

Creeping, properly so called, belongs only to serpents, and consists of a projection of the body backwards or forwards, produced by the alternate motion of one or several of the lower parts against the ground. The following modifications are exhibited in different instances. 1. Creeping by vertical undulations. 2. By horizontal undulations. 3. By two or three undulations of the posterior third part of the body, while the two anterior thirds are elevated vertically. 4. A sliding kind of crawling, by small undulations formed by the alternate approximation and separation of rows of scales placed transversely under the body. 5. The

REPTILES.

5. The same kind of motion, produced by the alternate formation and disappearance of folds in the skin of the sides.

6. Without any undulation, merely by the alternate approximation and separation of rings of the body.

The repulsive motions, by which reptiles move their bodies forwards in water, are nearly the same as they employ in jumping; but they must be much quicker. To rise in the water, they must strike back the water below and behind them, and diminish the breadth of their body, as much as possible, by carrying their swimming organs backwards after each stroke. Thus we see the frog, after striking, extend its long hind legs, so as to offer no resistance to the passage of the body through the liquid. The act of swimming offers the following modifications. 1. External swimming (on the surface of the water, breathing air) by vertical undulations, without swimming organs. The serpents. 2. The same by lateral undulations, assisted by the feet. Iguanas, lizards, &c. 3. Swimming under the surface, breathing externally; by four palmated feet, and without tail. *Hyla palmata* (*Rana maxima*, Linn.) 4. The same with four legs and no tail. Frogs properly so called. 5. The same with four feet, an elongated body, and depressed tail. Crocodiles, salamanders. 6. The same by means of four fin-like scaly members, and no tail. 7. Swimming under water, breathing by means of branchiæ.

The dragons are the only reptiles capable of flying. Their flight is nearly the same with that of the polatouche, or flying squirrel. Daudin, Hist. Nat. des Rept. t. 1. p. 256.

The Brain.—The brain of reptiles does not fill more than one-half of their very small cranium; hence its relative size to that of the body is very inconsiderable. Its proportion to the body is said to be, in the tortoise $\frac{1}{10}$, in the turtle $\frac{1}{15}$, in the coluber matrix $\frac{1}{12}$, in the frog $\frac{1}{17}$. Blumenbach justly observes, that anatomists have hitherto bestowed but little labour on the brains of the amphibia. The dura mater forms no processes in this order; the interval between it and the pia mater is filled with fluid; the brain is small and simple, and consists of five roundish eminences. Of these, the single one, placed at the front of the medulla spinalis, is clearly the cerebellum, as in all animals which have a nervous system. Whether the four others are to be regarded as the two hemispheres, and the thalami nervorum opticorum, is more doubtful. According to Blumenbach, the cerebellum does not exhibit the arbor vitæ.

All the parts of the brain of reptiles are smooth, and without circumvolutions. The optic thalami are situated behind the hemispheres, but are not covered by them. They contain each, as in birds, a cavity which communicates with the third ventricle. At the extremities of this ventricle, we observe the anterior and posterior commissure, but there is no soft commissure, nor tubercula quadrigemina.

In the tortoise the hemispheres form an oval. Their anterior part is separated from the posterior by a sulcus, and represents a kind of bulb, which serves as a root to the olfactory nerves. The size of this bulb is about equal to one-third of the hemisphere. The interior of the hemisphere is, as usual, excavated by a ventricle, and contains a substance analogous to the corpus striatum, and which pretty much resembles in its form that of birds.

The optic thalami are not larger than the bulbs of the olfactory nerves. Their form is nearly round. They extend downward and forward, under the hemispheres, to produce the optic nerve. The valve of the cerebrum is situated between them and the cerebellum. No tubercle is

either placed above it or before it, and it gives origin, as usual, to the fourth pair of nerves.

Before the optic thalami, and under the posterior part of the hemispheres, there is a tubercle which corresponds to that we have remarked in birds.

The cerebellum is nearly hemispherical. The fourth ventricle penetrates a considerable way into its substance.

In the frog the hemispheres are longer and narrower. The optic thalami are larger in proportion to the hemispheres. Their ventricle is very distinct. It is the contrary in salamanders, which have the optic thalami very small, and the hemispheres almost cylindrical.

The cerebellum of these two kinds of reptiles is flat, triangular, and lies posteriorly on the medulla oblongata.

In the serpents the two hemispheres form together a mass which is broader than long. The optic thalami are almost round, and one-half less than the hemispheres, behind which they are situated. The olfactory nerve has no apparent bulb. The cerebellum is exceedingly small, flat, and in the form of a portion of a circle.

In all these animals the inferior surface of the brain is nearly smooth. The optic thalami make no projection downward, and the pons Varolii does not exist.

Cuvier assigns, as the distinguishing character of the brain in reptiles, the position of the optic thalami behind the hemispheres. And he states the following as the points in which reptiles, fishes, and birds, differ from the mammalia. The want of corpus callosum, fornix, and their dependencies. Some tubercles, more or fewer, between the corpora striata and the optic thalami. The thalami containing ventricles, and being distinct from the hemispheres. The absence of any tubercle between the thalami and the cerebellum, as well as the absence of the pons Varolii. Reptiles and fishes are distinguished from the mammalia and birds by the want of the arbor vitæ.

The brain of the tortoise has been delineated by Caldesi, osservazioni intorno alle Tartarughe, tab. 2. fig. 5: that of the frog by Ludwig, de cinerea cerebri substantia; by Vicq d'Azyr in the Mem. d'Acad. des Sciences, 1783; and by Ebel, in his Observat. Neurol. ex Anat. Compar.; and that of the viper, by Vicq d'Azyr.

Origins of the Nerves.—The olfactory nerves arise, as in birds, from the anterior extremity of the hemispheres. The optic nerves seem to derive their origin from a common eminence, situated under the middle of the hemisphere. The other nerves exhibit no particularities as to their origin.

Distribution of the Nerves.—The olfactory nerve proceeds to the nostrils in this class nearly in the same manner as in birds; but it is longer. The canal which receives it is partly osseous and partly cartilaginous. The two canals have only one common aperture within the cranium. The olfactory nerves of reptiles are generally much more solid than those of the preceding classes.

The two optic nerves are joined together, as in the mammalia. There is nothing worthy of remark about the third, fourth, and sixth pairs.

Reptiles have the three branches of the fifth pair. In the sea tortoises the ophthalmic passes, some way, in the dura mater before it enters the orbit. It transmits filaments to the muscles of the globe of the eye, and particularly to the two lachrymal glands. The superior maxillary branch is the largest of the three. It is united to the inferior branch at its origin, but when it reaches the interior of the orbit, it separates from it to take another direction. It passes along the floor of the orbit, describing a very marked curvature, the convexity of which is external. A very great number of filaments proceed from the concave or internal

REPTILES.

side, which are lost in the lachrymal gland. The trunk is afterwards divided into two branches:—one internal, which corresponds to the sphenopalatine and sub-orbital nerve. It furnishes filaments to the palate and to the nose; and when arrived at the anterior part of the orbit, it proceeds outwardly and spreads upon the face. The other branch of the principal trunk is external; it passes also upon the floor of the orbit, to which it gives many filaments, and at length issuing from the inferior part of the orbit, it expands upon the face, anastomosing with the other facial nerves.

The inferior maxillary branch proceeds almost vertically downward to the posterior part of the orbit, before the petrous and articular process of the os temporum. In its course towards the lower jaw, it passes between the temporal and pterygoid muscles, to which it sends several filaments. Having arrived at the lower jaw, before the articular surface, it enters the oblong aperture, and divides in the substance of the bone. It forms several branches on the inner part of the jaw, which are lost in the muscles of the tongue, and on the outside some others which ramify under the skin.

The *facial* nerve exists in birds and reptiles, but its size is small, because these animals have no lips, and because their mouth, as well as a great part of their face, is covered with a horny or scaly substance, in consequence of which these parts have but little motion or sensibility. We find, however, some of the branches: they are not indeed easily followed in dissection, but their trunk always exists.

The *auditory* is united to the facial nerve as in the mammalia, and passes into a meatus auditorius, whence its branches go into the ear. They will be described in the account of the ear.

We have nothing remarkable to state respecting the *par vagum* or eighth pair of nerves in reptiles. We observe evidently that it is distributed to the lungs, the heart, the œsophagus, and stomach, and that it forms plexuses on these organs, in the same manner as the great sympathetic nerve produces them round all the arteries of the trunk. On leaving the cranium, the *par vagum* forms decussations with the lingual and glosso-pharyngeal nerves; they afterwards separate from each other: the glosso-pharyngeus is posterior, the *par vagum* in the middle, and the lingual anterior. The *par vagum* does not always come out of the cranium by a single hole; it is formed of two or three filaments, which afterwards rejoin, upon receiving a communicating filament from the glosso-pharyngeus, and one farther down from the lingual; the nerve then augments somewhat in diameter, and descends into the breast.

We have nothing to remark concerning the glosso-pharyngeal and hypoglossal nerves.

Tortoises have eight pair of *cervical nerves*, which are distributed nearly in the same manner as in mammalia. The three last pairs join in forming the brachial plexus. The green lizard has four pair of cervical nerves, but only the two last enter into the composition of the plexus. In salamanders and frogs the cervical nerves cannot be properly distinguished from the dorsal, as the animals have no ribs. A pair comes out between the first and second vertebrae, which is sent to the muscles of the inferior part of the neck, and under the skin that covers them. These nerves also afford some filaments to the shoulder. From this distribution they may be regarded as real cervical nerves. In frogs only two pairs enter into the composition of the plexus. In the salamander there are distinctly four.

We refer to the tables which indicate the number of the vertebrae in reptiles, in order to shew the number of nerves which issue from their foramina. The distribution

of these nerves is the same as in other animals, and to point it out would be only repeating what we have already described in man.

Nerves of the front Limbs.—In the tortoise the three last pairs of cervical nerves, and the first of the dorsal, proceed to the thoracic member, where they form a plexus in the following manner: the fifth cervical passes behind the other four pairs, crosses them in their course, and unites with them in its passage. It then turns round the scapula, which in this animal is articulated with the first dorsal vertebra. We shall return to the description of this nerve. The sixth cervical pair proceeds directly along the scapula on its internal surface: it is crossed posteriorly by the fifth, and towards the lower third of the scapula receives the seventh cervical pair. The seventh is slender, crossed by the fifth and the first dorsal pair, and united with the sixth, in the manner we have pointed out. The first dorsal pair partly joins the seventh cervical, almost at the point where it comes out of the vertebral canal; it is then sent to the muscles of the shoulder.

We shall now pursue each of the cords we have mentioned to their termination.

The large nerve produced by the fifth cervical pair, having arrived behind and near the true articulation of the scapula with the spine, divides into three branches; one, which is but a filament, appears to be distributed to the articular capsule; a second, which is very flat, and from the sides of which a vast number of lesser branches extend to the muscles of the skin, appears to take the place of the musculo-cutaneous; the third branch, which accompanies the muscles of the scapula under the skin, descends to the humerus, without producing any remarkable branches. At this place, however, it sends off several ramifications to the extensor muscles of the fore-arm. The trunk continues its direction forward, expands and loses itself under the skin, and may be followed as far as the hand: it may, perhaps, be regarded as supplying the place of the ulnar nerve.

The sixth pair of cervical nerves having, as we have shewn, assisted in forming the brachial plexus, passes along the internal surface of the scapula; about the lower third of that bone it receives the seventh pair; the nerve then becomes thicker, but soon after divides into two branches; one, which is slender, passes into the groove, between the furca and the clavicle, and then spreads over the articular capsule of the humerus, after furnishing numerous filaments to the muscles which surround it; the nerve may be regarded as analogous to the articular in man. The trunk of the nerve, which evidently supplies the place of the median, upon reaching the articulation of the humerus with the scapula, transmits filaments to the adjoining muscles. On arriving at the palmar surface of the fore-arm, it divides into three portions, two of which are on the ulnar side, and sink deeply into the muscles; the third, which is much larger, follows the radial side of the fore-arm, and at the base of the thumb proceeds to the palm of the hand, and detaches filaments to each of the fingers.

The seventh cervical pair unites, as we have stated, to the sixth, at the posterior part of the scapula, to form the median and articular nerves. We have, therefore, no occasion to return to its description. The first dorsal pair is lost in the muscles of the shoulder, and is not continued throughout the arm.

The brachial plexus of the lizard differs a little from that of the tortoise; it is formed by two dorsal, and the two last cervical pairs: the first of the cervical furnishes only one of its branches to the plexus; the other going to the neck.

REPTILES.

In the frog, the nerves, which are to be distributed to the arm, proceed from a very thick cord, which comes from between the second and third vertebræ: this makes the largest nerve in the whole body; it is soon after joined by a filament from the succeeding pair, with which it intimately unites; this cord proceeds towards the axilla; it sends off a branch, which passes above the shoulder, and is lost in the muscles of that part. The trunk continues its course to the arm, and very soon forms two principal branches, and besides these, it also sends some filaments to the extensors of the fore-arm, and the articular capsule of the head of the humerus.

Of these two nervous cords, one is directed forward upon the humerus, and represents the median nerve; it detaches some filaments to the muscles of the skin. Arrived at the fold of the fore-arm, the nerve plunges amongst the muscles, along with the tendon of the sterno-radialis, which supplies the place of the biceps; it afterwards divides into two branches, placed one above the other: the most slender is situated between the flexor muscles of the fingers; the larger upon the furrow, which indicates the union of the two bones of the fore-arm; they pass under the ligaments of the carpus; having reached the palm, the superficial branch is lost in the skin, which covers that part, and the deep-seated is distributed to each of the fingers, nearly as in man. It also furnishes some filaments to the muscles of the hand.

The other cord represents the radial nerve; it turns round the humerus, and furnishes, in the first place, some branches to the extensor cubiti; continuing to descend round the humerus, it arrives before the articulation with the bone of the fore-arm: it is afterwards divided; one of the branches is lost under the skin, the other passes under the back of the hand, and terminates on the convexity of the fingers. From this description it will appear, that the nerves of the arm in frogs very much resemble those of the wing in birds.

In the salamander, the nerves of the arm are distributed as in the frog, but the brachial plexus is formed by two cervical, and two dorsal pairs, if we may regard as dorsal vertebræ, those which sustain rudiments of the ribs.

There are no brachial nerves in serpents.

Nerves of the hind Limbs.—In lizards, there is only a small nervous filament, which proceeds from the femoral nerve, and supplies the place of the obturator. The femoral nerve is itself formed of the two last lumbar pairs, and passes above the bones of the pelvis to be distributed in the muscles of the anterior part of the thigh. The sciatic nerve is produced by the three pairs of nerves, which follow, and which also receive a filament from the last lumbar pair; the only cord they form proceeds along the inside of the thigh, subdividing in the muscles, and extending to the toes.

The distribution of the nerves in the abdominal member is nearly the same in the salamander; there are no differences, except in the manner in which the plexus is formed. The femoral is produced by a single lumbar pair, which transmits a branch to the sciatic plexus, formed by the two succeeding pairs.

In the frog, three pairs of nerves enter into the composition of the femoral plexus, before which they run the whole length of the ossa ilii, which are very long: when arrived at the thigh, the plexus sends off a nerve, which corresponds to the anterior femoral; it is distributed in radiated filaments to the fore part of the thigh. The rest of the plexus proceeds into the pelvis, and forms a large cord, which passes to the posterior part of the thigh, and may be

regarded as the sciatic nerve. A great number of filaments are afterwards detached from it to the muscles: about the middle and posterior part it divides into two branches, which pass under the ham, and represent the two popliteal nerves, the external and internal: these are afterwards distributed to the foot of the posterior leg, nearly in the same manner as to the human foot.

Great Sympathetic Nerve.—There is no description of the distribution of this nerve in reptiles, except in the mud tortoise; in which animal it was dissected by Cuvier. It is only distinct in the interior of the back-shell; it has a disposition analogous to that of the cervical ganglion. The pneumo-gastric nerve, however, adheres so closely to it, that they cannot be separated: we did not perceive any filament on the neck, which could be regarded as the trunk of the nerve.

On the peritoneum, and on the bodies of the vertebræ, there appear very distinct nervous ganglia, which are manifestly produced by the great sympathetic.

The ganglia are exactly similar to those of birds. There are two superior and two inferior filaments, which pass under the transverse process of the vertebra, that is united to the back-shell: from the internal edge of each ganglion, a splanchnic nerve proceeds, which forms a plexus round each of the arteries produced by the aorta; one is also sent to assist in forming the pulmonary plexus.

This nerve may be very easily traced to the internal parts of the first vertebra of the tail.

Physiology of the Nervous System.—The obvious differences of structure between the warm-blooded animals and reptiles, in this system; the exceedingly small brain and large nerves of the latter, contrasted with the slender nerves and large encephalon of the former, lead us to expect no less striking differences in their economy, than those which we actually discover. Are we to explain by this difference the little influence that the brain exercises over the other functions, and the great individual and independent vitality, if we may use the expression, of the parts, which appear in so many instances in the amphibia? The severest injuries, which in man or the warm-blooded animals would excite a sympathetic disturbance of every function, highly dangerous, and in most cases fatal, are borne with little apparent suffering, and restored with facility. (See the facts adduced in the physiology of the circulating system, to prove the tenacity of life in this class.) Can we explain in the same way the reproductive powers of this class? Blumenbach seems to consider the explanation sufficient. "The extraordinary strength," says he, "of the reproductive power in several amphibia, and the astonishing facility with which the process is carried on, must be explained, if I mistake not, from the great magnitude of their nerves, and the diminutive proportion of their brain. The former parts are in consequence less dependent on the latter; hence the whole machine has less powers of motion and displays less sympathy: the mode of existence is more simple, and approaches more nearly to that of the vegetable world, than in the warm-blooded classes: but, on the contrary, the parts possess a greater individual independent vitality. Since, in consequence of this latter endowment, stimuli, which operate on one part, or one system, do not immediately affect the whole frame by sympathy, as in warm-blooded animals, we are enabled to explain the peculiar tenacity of life, which is displayed under various circumstances in this class; viz. frogs continue to jump about after their heart has been torn out; and tortoises have lived for months after the removal of the whole brain from the cranium. The long continued power of motion in parts

REPTILES.

which have been cut off from the body, as in the tail of the water newt, and in fragments of the blindworm, may be explained upon the same principles." Handbuch der Naturgeschichte, ed. 6. § 98. p. 221.

The close connection between the brain, heart, and lungs in warm-blooded animals, in consequence of which the cessation of action in one very speedily stops the others, and consequently brings on general death, has been fully explained in various articles of this Dictionary; *viz.* DEATH, HEART, LUNGS, NERVOUS System.

Observations and experiments have not yet been sufficiently multiplied, to enable us to understand all the minutiae connected with this subject. But obvious phenomena, which we have already alluded to, shew us a vast difference in this respect between mammalia and reptiles. The interruption of respiration, which is fatal in two or three minutes in the human subject, does not stop the action of the heart and brain until after some hours in reptiles. The removal of the heart, or of all the blood from the circulating system, does not prevent the action of the brain, and thus prove fatal, until after some hours. And, lastly, the removal of the whole brain, or decapitation, which, by interrupting the action of the muscles employed in breathing, is almost suddenly fatal in warm-blooded animals, does not very greatly affect reptiles. At least, they only seem to die from inanition after the operation. Hence breathing cannot be under the immediate influence of the brain in these animals, for its interruption is fatal in a few hours. Le Gallois asserts that death follows much more quickly, when decapitation is effected below the occipital foramen, than above it, because in the latter case the part of the brain is left, which he has asserted to be necessary to respiration; *viz.* the origin of the eighth pair. (See his *Expériences sur le Principe de la Vie*, p. 42.) He does not, however, afford us the materials of drawing any accurate comparison, and he allows, that when decapitation is performed in the first vertebra of the neck, the animal survives the operation much longer than it can survive the interruption of respiration. He says, that salamanders live three or four months, and seem to die only from inanition, when decapitation has been performed above the foramen magnum.

To the small influence of the brain upon the nerves, Blumenbach is inclined to refer, in some degree, the low temperature of reptiles. Although he considers it now as certain, that the lungs are the source, and the oxygenous part of the atmosphere the material, whence the heat of living animals is derived, he ascribes to the action of the nervous system a considerable influence in exciting and supporting the evolution of animal heat. Specimen, p. 22.

The brain seems to exercise as complete and prompt a dominion over the voluntary muscles in these, as in warm-blooded animals. Their motions are equally lively, and the force of contraction does not seem at all inferior.

We know of very few facts that throw light on the intellectual faculties of reptiles. Yet there is sufficient evidence of their possessing memory and a capability of instruction. The frog and tree-frog can be taught to feed from the hand; and acquire a slight attachment to their master. (Dauid, v. 8. p. 88.) The rattlesnake, the hooded-snake (col. naia), the box, and the coluber natrix in Europe (at least commonly in Germany), are taught to dance, and exhibit various motions at command. (Kämpfer, *Amœnitates Exoticæ*, p. 565.) In the historical accounts of the religion of ancient Egypt, we learn that the priests of Memphis bred up crocodiles in their temples, and succeeded so far in depriving them of their ferocity, as to employ them in religious ceremonies. Besides the accounts of Herodotus,

Strabo, &c. on this subject, we have the authority of a respectable eye-witness concerning very surprising success in taming a crocodile; see J. Greaves's *Miscellaneous Works*, p. 525: and for the like success in the common toad, see Blumenbach, *Specimen*, &c. p. 27. We know not on what grounds the serpent gained his character for wisdom, intelligence, foresight; why he was selected as an emblem for the goddess of prudence, or chosen by the Epidaurians as the representative of Esculapius.

Of the artificial instincts, which are so frequent in the mammalia and birds, not even a trace is to be met with in the whole class of reptiles.

There is no *regular sleep*, or intermission of activity, in the organs of sensation and voluntary motion, recurring at stated intervals, in reptiles: unless, perhaps, in the turtles, of whom it has been reported by some.

Winter sleep, on the contrary, seems to prevail through the whole class. Herodotus observed this of the Nilotic crocodile, which, he says, passes four months of the winter without eating. Catesby has remarked it of the crocodile of Carolina; and Lacoudrenier reports, that those of Louisiana betake themselves to the muddy marshes when the cold comes on, and remain so torpid, that they may be cut without shewing signs of sensibility. But the warm days of winter re-animate them. *Journal de Physique* 1782, t. 20. p. 333.

No animals, except insects, are so sensible to heat as reptiles. The warmth of the sun seems to give them new life: as it increases, their vivacity and agility are augmented. Cold, on the contrary, benumbs them, and would be actually destructive, if they did not withdraw from its pernicious influence. They retire into the crevices of walls or rocks, the hollows of old trees, holes in the earth, or the bottoms of ponds, &c. to await the return of the genial season. The phenomena of this winter sleep are the same in reptiles, as in warm-blooded animals. The suspension of the actions of the nervous system is followed by an universal torpor of the other functions. As the brain and the organs of voluntary motion become inactive, the circulation languishes, respiration is barely continued, and vital temperature is reduced to the lowest degree.

Spallanzani found that when the temperature was reduced to $1\frac{1}{2}^{\circ}$ below zero, the heart of a serpent beat only twice in a minute, and respiration was suspended. (*Rapports de Pair avec les êtres organisés*, t. 1. p. 230.) In a temperature of 7° , the heart soon recovered its action, and beat ten or twelve times in a minute: in still higher temperatures, the pulsations were 28 or 30 *per minute*. (*Ibid.*) In the lethargic state, these animals changed the air very little. Frogs became equally lethargic in reduced temperatures: the heart beating very slowly, and the air being slightly changed. *Ibid.* p. 470.

Cold appears to be the immediate cause of this winter torpor; hence both reptiles and warm-blooded animals may be preserved in situations artificially warmed throughout the period of their winter sleep, without becoming torpid; but if the torpidity has commenced, they cannot be artificially awakened without danger. It is well known that the salamander, the water-newt, the tree-frog, and the alpine marmot, may be kept awake through the winter in a room warmed by a stove. Gleditsch witnessed the fatal effects of violent excitement in the winter sleep in the frog (*Mem. de l'Acad. de Berlin*, 1762, p. 17.): it has been observed also in the marmot, the dormouse, and the swallow.

It may be remarked further, of warm-blooded animals, as well as reptiles, that some species assemble together, and are gregarious in their torpidity, while others are solitary.

The

REPTILES.

The bat, swallow, frog, and salamander, exemplify the former.

Organs of the Senses.

Organ of Vision.—Reptiles, like all vertebral animals, have two moveable eyes occupying the cavities of the head called orbits, and possessing in their structure the same essential parts as in man. Their structure has not been much investigated: there is some information in a memoir of Petit, in the Acad. des Sciences, 1737; and an account of the tortoises in Caldesi.

They occupy the sides of the head, except in the crocodile, where they are placed above, between the cranium and jaw.

In the proteus they are covered by the integuments, and thus concealed until the latter are removed: this animal is, therefore, like the zemni or mus typhlus among mammalia, and consequently blind. All other reptiles have the sense of sight, and some possess even large and prominent eyes.

The tortoise has, at the anterior part of the scleroticæ, similar osseous laminae to those of birds. They are inclosed in that membrane, without being continued into its substance, and may be easily separated from it. There are similar laminae in the camelion and several other lizards, but they do not form the anterior disk, they merely surround the lateral part. Daudin has found this structure in the common iguana and the great tupinambis of America.

"In the tortoise," says Cuvier, "the ciliary processes project so very little, that we could scarcely recognize them, were it not for the elegant impression they leave on the vitreous body; but in the crocodile these processes are very beautiful, and very conspicuous: they are each terminated by a nearly right angle. I have observed these processes in the form of elongated threads in a large foreign tree-frog; there are also such, though not distinct, in the toad. I have not observed them in the common lizards, nor in the serpents.

"The iris of reptiles resembles that of fishes in its golden colours; sometimes it is red or brownish. The vessels are more visible than in fish; they form a beautiful network on the iris of the crocodile.

"The figure of the pupil varies; in the crocodile it is vertically oblong, as in the cat: in frogs rhomboidal. The tortoise, camelion, and common lizards, have it round; the gecko rhomboidal.

"The optic nerve in all reptiles passes through the membranes of the eye directly, and by a round hole, as in quadrupeds; it forms internally a small tubercle, from the edges of which the retina proceeds.

"The crystalline is more spherical in the turtle and frog, than in the mammalia: the ratio of its axis to its diameter is in the former 7 to 9, in the latter 7 to 8: these proportions are nearly those which it has in fishes."

Muscles of the Globe.—There are six in the tortoise, disposed like those of fishes: and besides, four small ones, which closely embrace the optic nerve, and spread over the convex portion of the sclerotic, after being interrupted by the muscle of the third eye-lid. The same structure is found in the crocodile.

In frogs and toads there is a great funnel-like muscle, which embraces the optic nerve, and is divided into three portions; its inferior fibres advance more towards the edge of the eye than the superior. There is only a single straight muscle on the inferior part, and consequently only a single depressor. There is one very short oblique muscle attached to the anterior part of the orbit, and inserted directly into the adjoining part of the globe. The muscle of the third

eye-lid is so close to the inferior part of the suspensory muscle, that it becomes stretched when the latter swells; which accounts for the elevation of the third eye-lid when the eye is lowered.

Blumenbach remarks, that no instance of the leucæthiopic formation, or deficiency of the colouring matter of the choroid coat and iris, has ever been seen in reptiles; although it is so common in the two warm-blooded classes, and in the human subject. Specimen, p. 27.

Many reptiles shun the light, lying hid by day, and coming out to seek their food at night. Others appear very fond of light, whether that of the sun, as the green lizard and green frog; or of artificial flame, like that of a candle, as the tree-frog.

It seems peculiar to the camelion to have the power of moving the two eyes at the same time in different directions; so that he is not necessarily obliged, like other animals, to bring the two optic axes into the same direction.

Eye-lids.—Reptiles vary singularly with respect to the number and disposition of their eye-lids: serpents have none; crocodiles and tortoises have three, and the third is vertical, as in birds: there are also three in frogs, but the third is horizontal like the other two. The third eye-lid is the part called membrana nictitans.

The crocodiles are remarkable for having bone in the upper eye-lid: in general there is only a single bit near the anterior angle; but in the crocodile palpebrosus the whole eye-lid is occupied by a plate divided into three pieces. See Cuvier in Annales du Muséum, v. 10.

The horizontal eye-lids of crocodiles and tortoises close exactly; they have each an enlargement at their edge, but no cilia; the third eye-lid is semi-transparent; it moves from behind forwards, and may cover the whole eye; it has only one muscle, which is analogous to the pyramidalis of birds: it is fixed in the same manner to the posterior part of the globe inferiorly. After having turned round the optic nerve, it repasses under the eye to send its tendon to that eye-lid; but there are neither the musculus quadratus, nor its sheath, as in birds.

In the other lizards there are also very remarkable varieties. The common lizards have, for eye-lids, a kind of circular veil extended before the orbit, and perforated by a horizontal fissure, which is capable of being closed by a sphincter muscle, and opened by a levator and depressor; its inferior part has a smooth round cartilaginous disk, as in birds; there is, besides, a small internal eye-lid, but it has no proper muscle; it is entirely wanting in the camelion, in which animal also the slit of the eye-lids is so small, that the pupil can scarcely be observed through it. The gecko has no moveable eye-lid; its eye is protected by a slight margin of the skin, as in serpents. A similar disposition seems to prevail in the scink.

Blumenbach has examined more particularly the structure of the part which covers the front of the eye in serpents. "These animals," he observes, "are commonly said to throw off the external layer of the cornea with the rest of their epidermis when they change their skin. On examining this matter more minutely in the coluber natrix, I find that that part of the epidermis, which is perfectly transparent and stretched before the eye, is not actually connected to the cornea, but separated from it by a small quantity of water. It is immovable, so that the globe moves behind it, as behind a window." Specimen, &c. p. 26.

In frogs and toads the superior eye-lid is only a projection of the skin, and almost immovable; the inferior is more moveable, and has a swollen edge; but the third, which moves from below upward, is most employed by these animals:

REPTILES.

mals: it is very transparent; it has one muscle situated transversely, behind the globe, which forms a thin tendon on each side of the eye, to be inserted into the free edge of the third eye-lid.

The salamanders have only two eye-lids, which are horizontal, fleshy, and little moveable; it appears that they may entirely cover the eye.

Reptiles vary as much with respect to their lachrymal glands as to their eye-lids.

The sea tortoises have a very considerable gland at the posterior angle; it is reddish, granulated, divided into lobes, and extends under the arch which covers the temple.

In the fresh-water tortoises we find two small blackish glands, which also exist in toads and frogs; but their excretory ducts have not yet been accurately observed.

Serpents, like fishes, have no gland in the eye; they have, however, a peculiar structure near the eye, the office of which is not very obvious; the following account of it is given by sir Everard Hume.

“An oval cavity is placed at the inner angle of the eye in some serpents, the opening into which is within the inner angle of the eye-lid, and directed towards the cornea. In this opening there are two rows of projections, which appear to form an orifice capable of dilatation and contraction. These cavities are lined with cuticle, which is shed with the rest of that integument. From the situation of these oval cavities, they must be considered as reservoirs for a fluid, which is occasionally to be spread over the cornea; and they may be filled by the falling of the dew, or the moisture shaken off from the grass, through which the snake passes.” *Phil. Trans.* 1804, p. 75. with a figure.

Organ of Hearing.—Such an organ is possessed by all reptiles. Its construction varies considerably in the different orders and genera: these varieties affecting the external or accessory parts, as the tympanum, ossicula, &c. more than the essential portion of the organ, its membranous labyrinth, on which the auditory nerve is expanded. No reptile has any external ear; and the crocodile affords the only example of a kind of external meatus. Frogs, testudines, and most of the lizard kind, have a tympanum and Eustachian tube; but these parts are wanting in the salamander, and most of the serpents. The ear of the turtle, tortoise, frog, lizards, and serpents, are described and delineated by Brunelli in the *Comment. Instit. Bonon.* v. 7. Comparetti has exhibited figures of the same subjects in his *Observationes Anatomicæ de aure interna comparata*, Patav. 1789, 4to. Scarpa has given most beautiful engravings of the ear in the turtle, crocodile, green lizard, salamander, viper, and blind-worm, in his *Disquisitiones de Auditu et Olfactu*.

The Labyrinth.—The membranous labyrinth of the ear, in reptiles, is, in general, composed, as in fishes, of three canals and a sac; but there are some species which have an additional part.

In the salamanders, whose ear, like that of fishes, consists of the labyrinth only, the three canals are situated above the sac; they are depressed superiorly, and form together a triangle which is almost equilateral; each has its ampulla, and the sac contains a body of the consistence of starch, as in the rays and sharks.

Frogs and toads differ very little from salamanders, with respect to the membranous labyrinth; they have the same parts in the same position, and their sac also contains one amylaceous substance: their three canals form nearly a complete circle, by their junction with the sac.

Crocodiles and lizards have also three canals, but they are larger, and each approaches nearer to a perfect circular form: the sac is situated proportionally more within the

head; its membranous parietes are furnished with several blood-vessels, which are particularly conspicuous in the crocodile. The solid parts it contains are three in number, and they are smaller, and even softer, than those of the chondropterygious fishes. Lastly, their labyrinth is rendered remarkable by having an additional part to those we have already described: this is the first vestige of the cochlea; it is the production of the sac, in the form of a cone slightly arched; it is directed, under the cranium, towards the middle line, and is divided into compartments, or rather canals, by a double cartilaginous septum; one apartment communicates with the sac; the other, which is a continuation of the first, reflected on itself, terminates at a very small hole, which is closed by a membrane that separates it from the cavity of the tympanum.

This organ is precisely similar to that which is found in all birds. Comparetti was the first who described it in lizards. It is very large in the crocodile, and may be easily prepared from young subjects.

It is more difficult to find this in the cameleon and the marbled lizard. A vestige of it may be observed in the serpents. The production which may be compared to this trumpet, or rudiment of the cochlea in the tortoise, is very similar to the part we named the sac, strictly so called, in fishes; and this resemblance consists not only in its form, but in the small amylaceous substances it contains: this seems to leave no doubt of the analogy between the sac and the cochlea in man, or of that between the part we call the sinus, and the vestibule. We must, therefore, judge of the perfection of the labyrinths of these different ears, by the degree in which the cochlea is developed.

Tortoises and serpents have the semi-circular canals, like other reptiles. In the tortoise they are proportionally very short.

The *osseous labyrinth* of reptiles resembles that of the chondropterygii; that is to say, it envelopes the whole of the membranous labyrinth, but in a manner more or less closely.

In the tortoise, the septum, which separates the vestibule from the cranium, is not ossified; it remains partly membranous. The membranous semi-circular canals are much smaller than the bony cavities containing them.

In the crocodile and other lizards, the osseous labyrinth closely embraces the membranous, or completely covers it by a thin and hard lamina.

Cavity of the Tympanum and its Appendages.—Among reptiles, the salamander has the labyrinth completely inclosed within the cranium, and deprived of all external communication, as in the fishes that have fixed branchiæ. But the other genera of the same order have all a fenestra, called *oval*, supporting an osseous plate, analogous to the bone called stapes in man. The lizard genus has another aperture, closed only by a membrane, and called *fenestra rotunda*.

The barrel, or cavity of the tympanum, cannot be said to exist in serpents: the stalk of the plate, filling the fenestra ovalis, is surrounded by the flesh, and its extremity touches the skin, near the articulation of the lower jaw.

In toads and frogs, the whole of its posterior part is membranous; it communicates immediately with the back of the mouth, by a large hole, which may be seen on opening the mouth of the animal. It is very small, and almost entirely membranous in the pipa, in which the labyrinth is connected with the fenestra ovalis by only a very long canal.

It is also membranous posteriorly and inferiorly in the common lizards, and in the cameleon: it communicates with the bottom of the palate by a short wide canal,

REPTILES.

The barrel of the crocodile may be divided into two parts: one external, which is very wide, and closed on the outside by the membrane of the tympanum, and the skin, but entirely furrounded by the bones; and one internal, which is separated from the former by a contraction, and which communicates with the two fenestræ, and with some cavities analogous to the mastoid cells of man, but much larger. One of these cavities is placed between the semi-circular canals, and the other is directed backward and outward. The barrel is situated towards the superior part of the cranium.

The cavity of the tympanum in the tortoise is placed more laterally: it is not so wide externally; and the contraction, which separates the external part from the internal, is less conspicuous, because the projection, which it forms, is rounded, and not acute, as in the crocodile. The internal portion is prolonged backward, in the form of a large round cell: in the bottom of the cavity, opposite to the membrane of the tympanum, there is a narrow canal, in which the ossiculum is sunk, and which communicates with the fenestra ovalis. The Eustachian tube is a canal of a moderate length, which proceeds downward, and a little backward, and terminates in the palate, behind and within the articulation of the jaw.

The Membrana Tympani and its ossæous Frame.—Animals which want the barrel of the tympanum, as fishes, salamanders, &c. have no membrana tympani. That membrane is also wanting in several reptiles that have a barrel, as the cameleon: the skin passes over the external aperture of their ear, without undergoing any change, either in its thickness or its structure; and the existence of the organ of hearing can only be ascertained by dissection. On removing the skin, and some portions of the muscles, we find, in some species, and particularly in the slow-worm (*anguis fragilis*), a kind of membranous expansion.

In the tortoise, the large external aperture of the barrel is closed by a very thick cartilaginous plate, which is itself covered by a scaly skin, perfectly similar to that of the rest of the head.

In frogs and toads, the membrana tympani is on a level with the head, and the skin that covers it becoming finer, it is rendered perceptible by an oval spot, which is smoother than the rest of the head, and usually of a particular colour.

In common lizards, the membrana tympani is also level with the head, but very thin, smooth, and transparent; for at that part the skin becomes as smooth and fine as the cornea of the eye.

In the crocodile, it is of the same nature, but more sunk into the head, and covered by two fleshy lips, which supply the place of the external ear.

In lizards, though the point of the cone formed by the membrana tympani projects less than in birds, it is also directed outward, as in them. The membrane is nearly plane in frogs and tortoises.

The membrana tympani is on a level with the adjacent parts of the head, and consequently is nearly vertical in all animals in which its situation is superficial; but in those which have it sunk, its inclination, whether considered with relation to the head itself, or to the external meatus, varies considerably.

It inclines obliquely upward, and to one side, in the crocodile.

The ossæous frame, to which the membrane is attached, is not marked by any prominent edge: it is interrupted posteriorly. Its great axis is vertical in the tortoise and the common lizards, and its anterior arch is more convex.

In the crocodile, it is a regular oval, the great axis of which is directed obliquely backward.

Ossicula Auditus.—The frog and the toad have two ossicula in the ear: one supplies the place of the malleus and the incus; it is attached to the membrana tympani by a slender branch, which forms an acute angle with the part that passes into the barrel: that part has the shape of a club; its internal extremity is the thickest, and articulates by a double surface to the second ossiculum, which corresponds to the stapes. The latter has a semi-elliptic form, and is applied to the fenestra ovalis by its plane surface: both these bodies, which are ossæous in other animals, are cartilaginous in the frog and toad.

Lizards and tortoises resemble birds, in having a single ossiculum with a thin hard stalk, and an oval or triangular plate (*columella*). It is attached to the membrane of the tympanum in lizards, and particularly in the crocodile, by a cartilaginous branch; but in the tortoise, its outward extremity is directly implanted in the cartilaginous mass, which corresponds to the membrana tympani itself.

In the crocodile, the plate is an elongated ellipsis, the great axis of which is situated longitudinally.

In the tortoise, the bone is enlarged in the form of a trumpet, and is applied to the fenestra by a regularly oval and concave surface.

Serpents have an ossiculum, but no membrana tympani. Its external extremity touches the bone that supports the lower jaw: it is surrounded by the flesh, and is applied to the fenestra by a concave plate, the edges of which are irregular.

In the cameleon, the plate also represents the wide end of a trumpet; its stalk becomes cartilaginous, and is lost in the flesh.

The fenestra vestibularis of salamanders is closed only by a small cartilaginous operculum, which has no stalk, and is concealed by the flesh.

Muscles of the Ossicula.—Little is known about these in reptiles. It appears that serpents, cameleons, and salamanders, are entirely destitute of them, and that they are very indistinct in the testudines. Comparetti has made some researches on this subject, but without any clear or satisfactory results.

External Meatus, &c.—All parts of the ear, external to the membrana tympani, are wanting in reptiles. In the crocodile only is there any appearance of an external meatus, the skin forming a kind of lip or operculum above the membrana tympani: the latter is entirely concealed, except when this covering is removed. This must be the part mentioned by Herodotus as the external ear of the crocodile, to which the Egyptians attached rings.

Distribution of the Nerves.—In reptiles and fishes, but especially in the latter, we can observe, still better than in warm-blooded animals, the constancy with which the branches of the auditory nerve proceed to the ampullæ of the semi-circular canals. In reptiles it divides before it passes into the ossæous labyrinth, which it enters by several holes.

Organ of Touch and Integuments.—It does not seem clear that reptiles possess the sense of touch, that is, the power of recognising, by any parts of their skin, the figure, hardness or softness, roughness or smoothness, of bodies. To the impressions of heat and cold, there is no doubt of their being sensible.

In no class do we observe so much variety in the nature of the integuments; the skin is different in almost every species. In many the structure is so singular, that if we judged by this alone, we should form them into separate classes. What

REPTILES.

a contrast does the shell or bony case of the tortoise form to the smooth skin of the tree-frog; how different are the annulated skin of the amphibia, the scaly covering of other serpents, and the integuments of the toad, rough and tuberculated.

Epidermis.—When we examine what parts of the body are covered with skin in the tortoise and turtle, we can recognize it at first sight only on the head, neck, limbs, and tail; the other parts exhibit to us merely an osseous box or exterior skeleton, inclosing the body. But, if we examine more attentively, we shall find this skeleton covered by an extremely thin epidermis, which may be detached in transparent laminae, similar, in figure, to the horny plates, and varying in its consistence in the different species. It resembles a smooth and transparent parchment in the *testudo centrata* of Boac (Daudin, t. ii. p. 153.) The epidermis covering other parts of these animals is a smooth thin layer, not essentially different from that of the frog and salamander, and detached in shreds several times in the year.

The epidermis of the salamander and frog is a soft thin membrane, covered with a mucous secretion; which answers a particular use in some kinds, as the rana calamita, enabled by its assistance to adhere to the smoothest bodies. This secretion, a simple and innocent mucus, is very different from another, which is found in many reptiles, possessing extremely powerful sensible properties; the latter is described under the head of peculiar secretions, in the latter part of this article.

The thin transparent cuticle of the frog, salamander, and newt, is very frequently changed, being detached in large portions. Blumenbach states that this change takes place in the summer months at least once a week. Specimen, p. 26.

The epidermis of lizards covers all their scales, and is detached in small dried portions, or in larger pieces. It forms also a thin continuous stratum in serpents, enveloping the whole surface, and spread over every scale and plate. It is detached annually, at a certain season, in a single piece, like a sheath. The cast skin (slough, *exuvia*) is turned inside out, so that its exterior surface is the part previously in contact with the true skin. The animal escapes at the mouth, which is the only opening by which it can get out of the sheath. The part corresponding to the jaws is first detached, and turned back, so as to expose to us the snout, covered by a new skin. As the head passes out of its sheath, the latter goes backwards in the same proportion towards the tail, and is thus at last completely inverted. The transparent piece corresponding to the eye (see an account of the eye) has its concavity outwards.

Rete Mucosum.—In all reptiles there is, under the epidermis, a mucous tissue, of which the colours vary very much. In the testudines, for instance, the skin which covers the feet and neck is not only differently coloured by the rete mucosum, but the symmetrical spots, which we remark on the scales, are produced by the same substance. This we discover by dissection. The thickness of the skin greatly diminishes as it approaches the breast-plate and the back-shell. It passes below the scales which cover those parts, and which are, themselves, covered by the epidermis and rete mucosum; the variegated colours of which form the spots which we observe through the transparent parts. A rete mucosum is equally found in the lizards, serpents, salamanders, frogs, &c. It is variously coloured in each species; and it presents often the most beautiful and charming tints. We find in this class almost all the known shades, even blue, bright red, orange, pearly, gold and silver.

Reptiles are remarkable for the changes of colour which they exhibit, according to the season or climate in which they live, or to temporary affections of various kinds. In this way theameleon has been most celebrated, and has afforded a very trite subject to poets and moralists. The changes are, in reality, very remarkable, and are particularly noticeable when the animal passes from the shade into the sun, or *vice versa*, when he is touched, or any thing placed round him, &c.

This property, however, is, by no means confined to theameleon. Brown long ago observed it in several species of lizards (Natural History of Jamaica, p. 462.) and it occurs also in reptiles of these climates. The green iguana, the agame, and the green lizard, are sometimes green, sometimes brownish in their colour. The former is particularly observed in the copulating season; and is lost in the cold and rainy parts of the year. The common tree-frog of Europe exhibits various tints from the brightest emerald green to grey, blueish, violet, or brown. Other frogs and salamanders change their colours also, particularly about the copulating season.

The Papilla.—Reptiles resemble birds with respect to the papillae; we find none except under their feet; they are very thick, and projecting in several species of lizards, and particularly in theameleon. We cannot distinguish them in the sea tortoise, which have the feet in the form of fins. They do not exist in serpents, or at least have not the form of papillae.

Cutis.—Reptiles which have the body unfurnished with scales, or only partly covered by them, have a very compact and dense skin. We have an example in the tortoises, salamanders, frogs, and toads. In the two last genera, in particular, the cutis is rendered remarkable by not adhering to the body in all its points, as in the other animals, in which it is intimately united with the cellular substance. In those genera, however, it adheres only at the edges of the mouth, in the middle line of the body, the arm-pits and the groins. In all the other parts the body is free within the cutis, which incloses it like a sac.

In lizards and serpents we find, as in fishes, a strong cutis under the scales, even adhering very closely to the muscles.

Cutaneous Muscles.—There is no cutaneous muscle on the trunk of frogs, because the skin does not adhere to that part of their body. Under the throat, however, we find some fibres, which are attached to the margin of the jaw, and inserted into the cellular substance that unites the skin to the origin of the breast.

In tortoises the cutaneous colli is very visible, and seems to be formed of two parts; it is extended from within the concavity of the lower jaw to the bottom of the neck, at the anterior part of the breast-plate. A middle cellular line unites it with the muscle of the other side; it takes its origin from the transverse processes of the cervical vertebræ. Being spread over all the muscles of the neck, it serves as a girdle to them; in its lower part it is perforated by the sternomastoideus, which, as we have already observed, arises from the lateral parts of the breast-plate.

Secretions of the Skin.—Among reptiles, those that have scales, as snakes and lizards, have the skin almost dry; but those with naked skins, as salamanders and frogs, have the surface of the body always copiously lubricated with viscid matter.

Toads and salamanders have even the power of augmenting the secretion of this liquor, and of making it exude, like a dew, through the pores of the skin.

The cutaneous glands are more visible in cold-blooded animals, than in the mammalia.

REPTILES.

The salamanders have several glands ranged along the back, which form elevations or lumps on the skin.

The toads have them scattered irregularly on the whole surface of the body; we observe, in particular, two which are very large, behind their ears; these glands produce an acrid humour, which is a poison to very small animals.

In lizards, we observe a very regular row of small pores, which also yield a viscous humour.

Absorption of water by the skin of the frog.—Townson found that the frog, and tree-frog, when placed on a moistened paper, could absorb the moisture so rapidly, as nearly to double their weight in two hours, under certain circumstances. He states that they do not drink, but take in all their fluid in this way. (See his tracts and observations in natural history.) Daudin has verified the observation. He kept two frogs without any fluid for seven days, and then placed them in a bottle on moistened sheets of paper. In two hours they had nearly doubled their weight. *Hist. Nat. des Reptiles*, tom. i. p. 115.

Fingers.—The number of the fingers, and their flexibility, vary more in reptiles than in all the other classes.

Common lizards have, in general, five fingers, of different lengths, well calculated to embrace objects in every direction. Some, as the crocodiles, have them palmated, at least in the posterior feet. Others, as the gecko, have them invested inferiorly with imbricated scales.

Theameleon has them united by the skin, as far as the nails, in two parts, which form the forceps. The skin of their inferior surface is furnished with sensible papillæ. The long lizards, called seps and chalcides, have only three very small toes. The salamanders and frogs have them naked and destitute of nails. In tree-frogs, the extremity of the toes is enlarged into a spongy disk, capable of adhering with force to bodies. In tortoises, the toes are palmated. Lastly, the serpents are completely deprived of feet and toes.

The long separate toes of the batracian order, and of several lizards, seem well enough calculated to serve as organs of touch; they might be applied to objects, and would surround them in various ways. They seem, however, to be employed merely as instruments of motion.

“It has been said of serpents (observes Blumenbach), with more ingenuity than truth, that their whole body is a hand; by which they gain just notions of the tangible properties of bodies. There is much more foundation for stating that the sense of touch, which is here meant, does not exist in any of the amphibia.” *System of Comparative Anatomy*, p. 319.

Among the reptiles the scales vary greatly, according to the genera. In tortoises they are plates of a horny substance, which are very hard and dense in the greater number. But in the testudo coriacea, and several others, they are soft and flexible: sometimes these scales are imbricated, as in the hawk's-bill turtle; and then they are smooth, or channelled longitudinally; at other times they form compartments of different figures: in the latter case they are more or less convex, and surrounded with furrows, or concentric channels, in the midst of which are points, which are either scabrous, elevated, or blunt, as in the species named *geometrica*, *græca*, &c.

In the crocodile the scales are bony, arranged in transverse bands, and situated, in respect to each other, like the stones of a pavement. In the other lizards and serpents they consist of horny substance, and present almost every possible variety of form and arrangement.

Organ of Smelling.—This is less completely developed in the amphibia than in the two warm-blooded classes of vertebral animals. The sense of smelling is the most imperfect of the

senses in this class, says Daudin, if we may judge by the structure of the nostrils. Reptiles do not seem to employ their smell in discovering or selecting their food, or for any of the purposes to which the faculty is subservient in other animals.

We find, however, in the whole class, nasal cavities opening on the snout in front, and on the palate behind, lined with a vascular pituitary membrane, on which olfactory and nasal nerves are distributed.

There are also different projecting laminae within the nose; but they consist of folds of the internal membrane, and are not sustained by osseous parts. The tortoise has three laminae, which divide the nasal cavity into several fossæ. The middle one corresponds to the external aperture of the nostrils; between it and the next there is an oblique canal, which leads to the posterior nares. We find only some tubercles in frogs, and other small species. It does not appear that any researches have been made respecting the parts in the crocodiles.

The olfactory nerve differs in reptiles little from that of birds, as to its origin and course; it differs less in its distribution, since it also divides, according to Scarpa, upon the septum, and the membranous fold corresponding to the superior turbinated bone, without proceeding farther.

The external nares of reptiles, more or less approximated, and susceptible of contraction and dilatation, are usually furnished with only some fleshy strata, which dilate or contract their entrance. This is observable in the greater number of lizards, which differ from each other only as to the position of their external nares. They are closest to each other in the crocodiles. The tupinambis, the stellions, and the cameleons, have them more removed, and situated more laterally. In the salamanders they are exceedingly small. In frogs we observe a small tube, the motion of which is very apparent, because it is extremely useful in respiration, as we have already shewn. The tortoises have also two very small approximated nostrils. In the matamata, and one or two other species, they are situated at the end of a short cartilaginous proboscis. The external nose is also rather elongated in some serpents; for example, in the *vipera ammodytes*, and the *coluber naja*. In the rest of this order there are small lateral nares, capable of slight extension. In the rattlesnake, and some others, there is a small blind hole, near the nose, on each side; we have described it under the head of peculiar organs. See Scarpa de *Auditu et Olfactu*, for a description and figures of the nose in the turtle and viper.

The Organ of Taste.—All reptiles possess a tongue, but whether they have the sense of taste is not so clear. As they all swallow their prey whole, there seems to be little room for the exercise of taste. We have already spoken of the tongue, in the account of the salivary glands; and have entered further into a consideration of its mechanism and moving powers in our description of the organs of mastication and deglutition.

Substance of the Tongue.—Reptiles vary greatly with respect to the tongue, as well as in many other circumstances. The tongue of toads and frogs is entirely fleshy, attached to the lower jaw, and, in a state of repose, inserted in the mouth.

In salamanders, it is attached as far as the point, which is not moveable, and the whole tongue is only free on its lateral parts. Crocodiles have it attached to the lower jaw, both by the edges and the point; and authors long supposed that this animal had no tongue. It is entirely fleshy in both these genera.

The stellions and the iguanas have a fleshy tongue, which possesses nearly the same mobility as that of the mammalia.

REPTILES.

The scinks and geckos differ only in having the tongue notched at the extremity; and in that respect it resembles the tongue of the slow-worms, to which, in general, the scinks are very much allied.

In common lizards, the *tupinambis*, or monitor, &c. the tongue is singularly extensile; it terminates in two long flexible points, though semi-cartilaginous; it completely resembles that of serpents, if we except the slow-worms and the *amphisbæna*, which cannot elongate their tongue, but which have it flat, and only forked at the extremity.

The *cameleon* has a cylindrical tongue, which may be considerably elongated by a mechanism analogous to that which takes place in wood-peckers.

Structure of its Surface.—The tongue of the tortoise is furnished superiorly with long, soft, close, conic papillæ, which give it the appearance of velvet.

In the crocodile they are very short, and represent rather slight rugæ than papillæ. They form, on the contrary, a very distinctly villous surface in the iguanas and the steliions. The tongue of the *cameleon* is furnished with deep, close, and very regular transverse rugæ; in the lizards, with extensile and forked tongues; and in the serpents, that organ is singularly smooth, and as it were horny towards its points.

The salamanders have, like the iguanas, a fine villous surface to the tongue; but in the frogs and toads the surface is perfectly smooth to the eye, and always mucous.

No reptile has two kinds of papillæ, nor glands with a calyx.

Peculiar Organs and Secretions.—Many amphibia produce singular and specific odours, particularly when irritated. In the water newts the smell has been compared to that of chopped parsley; in toads to garlic; in the crocodile there is a very strong smell of musk; and several tortoises have this musk-like smell. A singularly fetid odour is produced by the rattlesnake, when angry. May we suppose that this is a defence against hostile attacks, in the salamanders and water newts, as it seems to be in the *viverræ*, and some frogs?

It may probably serve in spring, as Blumenbach suggests, as a means of venereal excitement. For if, after handling female toads for some time, the hand is plunged into water, where there are male toads, they flock instantly to the spot, and closely embrace the fingers. Specimen, p. 29.

The notion that this odour is employed by the rattlesnake to suffocate, fascinate, or in any way whatsoever to act on the animals which form its prey, is entirely ungrounded, as we have already explained.

There are generally manifest organs for the secretion of the substances in which these properties reside. Small granulated tubercles are seen under the thighs of the lizards, the chalcides, and the marbled iguana of Surinam, and near the anus of the *amphisbæna*, producing, particularly in the coupling season, a fluid, and smelling like dry hay.

Musk Gland of the Crocodile.—It lies under the skin of the lower jaw, on each side, about its middle. It is a small gland, of a homogeneous whitish tiffue, and covered by a tendinous sheath. It secretes an unctuous blackish-grey fluid, smelling most strongly of musk, and collected in a small bag, which opens externally by a large orifice.

Anal Glands have also been observed in the crocodile and alligator, as well as in several serpents. They may be seen of considerable size in female colubres, under the tail behind the cloaca, in the part occupied by the penes of the males. They contain a thin yellow substance. Tyson has described them in the rattlesnake. Other snakes have been described as producing powerfully fetid odours from the mouth.

Poisonous and Acrid Secretions.—There is a striking difference in this respect between warm-blooded animals and reptiles: none of the former produce any thing poisonous, unless we should make an exception concerning the liver of the *urfus arctos*, which is described by Ger. de Veer, one of the unfortunate sufferers, to have been nearly fatal when employed as food by Heemskerck and his companions, compelled to winter in Nova Zembla. Blumenbach's Specimen, p. 30.

Besides the terrible poison with which so many serpents are armed, already described in our account of the teeth, there are several more or less actively hurtful secretions in this class.

The glands or crypts under the skin, forming the cutaneous eminences in the salamander and toad, produce an irritating fluid, which they seem to have the power of excreting at pleasure. Blumenbach describes the acrimony of this fluid in the *rana bombina*, from his own experience of its effects. Having cut his hand while handling some of these animals, and applied it to his mouth to suck the wound, he found a caustic heat suddenly pervade the tongue and fauces, like what is produced by chewing the bark of the laurel; and it continued for several hours. P. 24.

It seems to be an analogous fluid in the salamander, by means of which this most innocent little animal, so unjustly deemed venomous, can extinguish a few coals when placed in them. But the contortions of the body sufficiently attest the pain produced by this cruel experiment, which is soon fatal, if prolonged. The fabulous notion of the ancients, that this little reptile can live in fire, is well known; and Benvenuto Cellini has ventured to assert the truth of it, on the faith of his own experiments. See his Life.

The notion of the salamander being able to live in fire is the more extraordinary, when we contrast it with the fact, that it has been found in cakes of ice, and after remaining frozen for some days, recovered. So that it can actually survive congelation.

Dr. Barton of Philadelphia has named an aquatic salamander, which he found near that city, *salamandra venenosa*, from the nature of the fluid which exudes from the tubercles of its back. Daudin, tom. viii. p. 229.

The gecko produces a poisonous fluid of considerable activity. "It exudes (says Hasselquist) from the lobules of the toes; the gecko seeks for places and objects impregnated with marine salt, and passing several times over them, leaves its venom behind. I saw in 1750, two women and a girl, who nearly died in Cairo from eating cheese which had been thus poisoned. I had another opportunity of noticing the acrimony of this fluid, in the production of red, inflamed, and itching pustules on the hand of a man, who endeavoured to catch the animal." The French naturalists, attached to the Egyptian expedition, confirm the report of Hasselquist. Daudin, tom. iv. p. 110, 111.

Rattle of the Genus Crotalus.—This singular organ consists of many pieces, from one to thirty, or more, perfectly similar, not only in form, but often also in size, composed of a brittle, semi-transparent, horny substance, similar to that of scales. The piece immediately connected to the body forms a small sheath, moulded on the last vertebræ of the tail, which it incloses, and from which it is separated only by a thin membrane. Its surface presents three circular risings, corresponding to three elevations of the vertebræ: the first, or nearest to the animal's tail, is the largest, and the two others decrease successively. All the pieces are encased one in the other, the posterior two-thirds of each being enveloped by the following. Of the three risings or rings on each piece, the anterior only is visible, the two posterior

terior being concealed by the following piece. The last, or extreme portion, has all its three rings visible; and the organ consists, externally, of this piece, and the first rings of all the others. The two last rings of each piece, included in the two first of the succeeding, retain it in its place; but, as the diameter of the former is less than that of the latter, each piece is quite loose, and plays freely about that which it envelops. None, except the first, is united to the skin of the animal, or connected by any muscle, nerve, or vessel; it is, therefore, merely an exterior covering, moved, as any foreign body would be, when the end of the tail is agitated.

The different pieces of the organ are formed successively on the skin of the tail, receiving from it the materials necessary for its development, and adhering to it until its growth is complete. A second piece, entirely similar to the first, is formed under it, and detaches it from the end of the tail. It is pushed backwards, leaving between its edge and the skin of the tail an interval occupied by the first ring of the new piece, of which the second and third rings are covered by the first piece. The latter is retained by this connection, but plays freely round the first piece. A third piece is formed under the second, as that was under the first; pushing the second backwards, but retaining it by its two posterior rings being included in the cavity of the second piece.

If the vertebræ of the tail continue of uniform diameter, all the pieces will be of the same size, and the rattle, consequently, is of one breadth throughout. On the contrary, if the vertebræ grow while the rattle is being formed, the pieces increase in size, and thus the rattle tapers to its end.

It is evident, from the preceding description, that one piece only can be formed at each partial moulting of the end of the tail; but as we do not know whether these moultings coincide with the general separation of the epidermis from the body, nor the periods of their recurrence, the number of pieces not only affords no proof of specific differences, but also indicates nothing about the age of the animal. Lacépède, *Hist. Nat. des Serpens*, 12mo. t. 2. p. 217.

Horns, &c. of other Serpents and Reptiles.—The Egyptian cerastes is so named, from its two moveable, pyramidal, four-sided, curved horns, about two lines in length, placed above the eyes. They consist of successive strata, of which the exterior separates like an epidermis, exhibiting always four grooved sides. The exterior stratum separates thus with the animal's skin, like the epidermis of the scales, which thus resembles entirely in its texture. Lacépède, *ubi supra*, t. 1. p. 256.

In the batracian order, the horned frog has a conical horny elevation above each eye; and the rana margaritifera a peculiar hard crista on each side of the head.

The cecilia ibiara has two small tentacula or cirri, scarcely visible near the nostrils; and the serpent, which Lacépède has named erpeton tentaculé (*Annales du Muséum*, t. 2. p. 280.) has two fleshy appendages, covered with scales, extending from the end of the snout horizontally forwards. Is there any probability that these parts in the cecilia and erpeton are organs of touch?

Facial Pouches of Serpents.—A small bag has been observed in the rattlesnake, in sixteen colubres, and three boas, between the eye and the nostril; it has a rounded form, resting in a hollow of the bone, in shape not unlike the orbit. A small orifice behind the nostril leads to it. These bags, which are lined with cuticle, have their covering cast with the rest of the animal's skin. The cavities in question

were noticed in the rattlesnake by Tyson, *Phil. Transf.* v. 13. p. 26; and they have been since described and delineated by Dr. Ruffel and sir Everard Hume. (*Phil. Transf.* 1804, p. 70.) The latter anatomist discovered nothing like a secretory apparatus about them, nor any thing that could lead to conjectures concerning their office. They appear most analogous, in situation and structure, to the small bags of the deer and antelope, called by the French *larmiers*.

We conclude our review of the structure and physiology of reptiles with the summary of the principal differences between their economy and that of the warm-blooded classes, which terminates the excellent "Specimen" of Blumenbach.

"Et calidis quidem animalibus a prima inde formationis origine ad ultimum usque vitæ halitus phlogisticus ut hodie audit processus. Mammalium foetui placenta adminiculo, quæ foetale phlogiston materno elemento igneo commutat. "Vtrum eo major ab altera parte simplicioris istius vitæ tenacitas, quod parte una affecta, systemate uno afflicto, non tam facile reliqua in consensum trahantur.

"In universum ergo vita magis vegetativa, reproductioni—ut per utrumque organicum naturæ regnum consistat—longe magis opportuna, quam quæ altioris ordinis facultatibus, consensibus, et complicatæ conspirationis subtilitate viget." P. 36.

Anatomical Description of the Proteus Anguinus, and Siren Lacertina.—See Cuvier, *Récherches sur quelques Reptiles douteux*, inserted in Humboldt's *Recueil d'Observations de Zoologie et d'Anatomie comparée faites dans son Voyage*, t. 1.

By the word *amphibious*, applied to animals, naturalists have meant to designate the power of living, and particularly of breathing, equally well in water and in air. In this sense it cannot be applied, with propriety, to any of the animals who have received the appellation from the ancients, and most modern naturalists. Without speaking of the otters and hippopotami, which are true aerial quadrupeds, vi sitig the water merely in search of food, the seals and cetaceous

REPTILES.

animals, compelled by their organs of motion to pass the whole, or nearly the whole of their life in water, can absolutely breathe air only.

All the reptiles to whom Linnæus subsequently transferred this name of amphibious animals, are similarly circumstanced in their adult state; they can only breathe air, whether they live constantly in this element, as the lizard kind, or betake themselves, for a longer or shorter period, to the water, as the frogs and salamanders. On the other hand, the cartilaginous fishes, which this same naturalist had joined to the reptiles, like all other fishes, can only breathe by the intervention of water; they have only gills; and it is by having represented as lungs the forked swimming bladder of some of them, that Dr. Garden caused the mistake of Linnæus.

The larvæ or tadpoles of the batracian reptiles only, that is to say, of the salamanders and frogs, the tree-frogs and toads, have both branchiæ and lungs; breathe, at least for a certain time, both the air in its elastic state, and that which is contained in water; consequently participate equally the nature of aerial and aquatic animals; and may, therefore, without impropriety, bear the name of *amphibious* in its most strict acceptation. But with these it is only a transitory, and with some perhaps only a momentary state. As their lungs are developed, their branchiæ are obliterated, and they entirely lose the latter, often even before reaching their full size, and particularly before they are capable of reproduction. Such, at least, is the result of observations on all the tadpoles of these climates, on all which it is possible to follow in their various developments.

But naturalists have observed three other animals, uniting, like our tadpoles, the two kinds of respiratory organs, not appearing to lose any of them at any epocha of their lives, and of such form and size, that it is said in the countries which they inhabit, no perfect reptile is known, of which they could be the larvæ. Are these creatures perfect animals—true permanent amphibia? Should they be considered an intermediate class between reptiles and fishes? We proceed to examine this question, observing, in the first place, that the structure of the circulating organs in the common tadpoles, which has been described in a former part of this article, must be kept in view as a point of comparison.

Anatomy of the Siren Lacertina.—This animal is common in the rivers and marshes of South Carolina, and is remarkable for possessing only the fore feet. Dr. Garden sent an individual to Linnæus, accompanied with a description, in which he mentioned the simultaneous existence of branchiæ and lungs, and declared that there is no salamander in Carolina large enough to have been produced from the siren. Hence Linnæus determined to establish for it a particular order of reptiles, the amphibia meantes. Nearly at the same time it was described in the Philosophical Transactions by Ellis, whose description was accompanied with an anatomy of the animal by Mr. J. Hunter. Yet several naturalists contested the result of these examinations. Pallas, Hermann, Schneider, and others, considered that it might be a larva. Camper, on the faith of an imperfect specimen, in which no lung could be found, concluded it was a fish, (Kleine Schriften, tom. iii. pl. 1. p. 20.); and Gmelin, on his authority, classed it among the eels.

Cuvier has had an opportunity of dissecting and describing it. His account, which settles the disputes satisfactorily, is contained in the Recherches already quoted, and has furnished the materials of the following description. The facts are represented in the 11th and 13th plates of the first volume of Humboldt's Recueil d'Observations de Zoologie et d'Anatomic comparée. The length was half a metre,

but it reaches sometimes between 30 and 40 inches. The body is much like that of an eel. The anus is at 15 centimetres from the posterior extremity. The head is not separated from the body by a neck: it is rounded, and terminated by an obtuse snout. The mouth is small, and the lips, which are not considerable, are not supported by any bones, as they sometimes are in fishes. The nostrils are two small holes near the edge of the upper lip. The eyes are placed above the angle of the mouth: they are round, small, without eye-lids, and only visible because the skin, in passing over them, becomes transparent. You may skin the head, like that of an eel, without injuring the eye-ball.

The openings of the gills are three vertical slits placed in succession behind the head: through them the water from the mouth is discharged. But there are no gills within, as in the lamprey for example; although Garden, Ellis, and Camper supposed it. The only branchiæ are three tufts or fingers, attached to the superior angle of the slits, to which Ellis and Garden gave the name of opercula, but of which Linnæus recognized the true nature. There are surely only three on each side, of which the first is the smallest, and the third the largest. The different statements concerning their number, which embarrassed M. Schneider, arise from the name having been given to different parts. For example, Linnæus, who rightly deemed the tufts to be branchiæ, reckons three, without opercula (branchia ad latera colli utrinque tria, exserta); but Garden, who conceived that the branchiæ were connected to the arches, says there are four, with three opercula, or one operculum of three lobes.

Each of the tufts consists of a large fleshy and conical pedicle, of which the inferior edge is divided into two rows of appendices, which are themselves again twice divided in the same manner. The animal must have the power of moving these branchiæ in every direction: the net-work of branchial vessels is expanded on their ramifications.

The fore feet, short and slender, are placed a little behind the branchial apertures. There are four fingers, of which the last phalanges are pointed, but not furnished with nails. There is not the smallest appearance of scales on the skin.

Osteology.—Although the individual examined by Cuvier had not reached its full size, ossification was considerably advanced. The cranium, lower jaw, and spine, were perfectly ossified. On the large bones of the arms there were epiphyses, and the scapula was almost entirely cartilaginous. The latter bone remains constantly in this state in the salamanders. The branchial arches were entirely cartilaginous, and probably continue so, as no point of ossification could be observed, although the os hyoides and its branches were already almost completely hardened.

From the head to the end of the tail there are ninety vertebræ: the anus is opposite to the forty-fifth, yet it is far from being opposite to the middle of the body, because the vertebræ of the tail, particularly towards its end, are much smaller than the others. The land salamander has thirty-eight, and the aquatic about forty. The pelvis is suspended opposite to the fifteenth or sixteenth, in the former; to the fourteenth or fifteenth, in the latter. There is not the smallest vestige of pelvis or hind leg in the siren: there is not even any germ of these parts, although they exist in the tadpole at all ages. It is, therefore, very certainly never destined to have hind legs. There is a kind of imperfect pelvis, even in the ophifaurus (anguis ventralis, glass-snake), a true serpent, though analogous to the lizards in some points, but never possessing hind legs.

Eight vertebræ only of the siren, from the second to the ninth,

REPTILES.

ninth, support small ribs, or rather very short false ribs. In the land salamander there are twelve or thirteen, and in the aquatic eleven. These small ribs, lost among the muscles, are only observed in the genus of serpents called cæcilia, where they exist in great number.

The individual vertebræ are very differently shaped from those of salamanders, frogs, and cæcilia. The body is terminated before and behind by a hollow cone filled with cartilage, which unites it to the adjoining bones, as in fishes. There is a small longitudinal prominence below; and above, a crista holding the place of the spinous process, and bifurcated behind. The four angles of the superior surface are occupied by the articular apophyses, of which the anterior have their articular faces turned upwards, and the posterior downwards. The transverse processes are formed of two triangular plates: one, inferior and horizontal, comes off from the whole side of the body of the vertebræ; the other slants backwards, and reaches from the anterior articular process to the posterior edge of the preceding. At the extreme point of their union we find the surface to which the rudiment of rib is articulated, in those vertebræ which have ribs.

None of the allied genera resemble the firen in the form of the vertebræ; and their singular shape would alone be sufficient to authorize us in constituting a separate genus for this animal. The head leads equally to the same conclusion, being entirely different from that of the salamander, and other reptiles. The nostrils, simply excavated at the sides of the snout, do not penetrate into the mouth: neither the orbit nor the temporal fossa is closed below. Hence the upper jaw-bone does not form a complete bony circle; its anterior part only is formed by the intermaxillary bones, and has no teeth. Thus the firen has only palatine teeth attached to the two plates, and not implanted in the palate. The prominence, having the surface for the articulation of the lower jaw, is much shorter than in the salamander. The lower is articulated with it by a convex surface, shaped like the segment of a sphere: its coronoid process is very short; each of its branches is composed of three pieces at least. The teeth are attached to their internal surface, and not implanted in their edges. The head is articulated to the neck by means of two condyles.

The bony apparatus of the branchiæ resembles that of fishes, with a few slight differences. A longitudinal bony piece bears, at each of its extremities, a pair of transverse portions. Each of these anterior portions is joined to a cartilage, which ascends behind the head, suspended by a strong ligament to the sides of the occiput: it is analogous to the piece which supports the radii of the branchiostegal membrane in fishes. But here there are no radii; and there is even a solution of continuity between this piece and the first arch of the branchiæ. This first arch, the largest of all, is joined to the posterior transverse piece mentioned above. The three others are joined to a third bony piece, similar to the preceding, but suspended behind it, and not articulated to the longitudinal piece. These four arches are simply cartilaginous. Their superior extremity is suspended to the second rib by a ligament, but not articulated to it. Their edges exhibit a series of small fine denticuli, which border the three branchial apertures: the anterior edge of the first arch, and the posterior of the last, not concurring in the formation of any opening, have none of these denticuli. The skin is immediately attached to these arches, and they support nothing, as we have already stated, analogous to the branchiæ of fishes. The tufts, which have no bone in their interior, are the only branchiæ.

The osteology of the legs is the same as in the sala-

mander: it comprises a slender scapula, terminated above by a cartilaginous dilatation; a large cartilaginous plate, which may be regarded as a double clavicle, analogous to that of the frog, the use of which is to protect the front of the chest; a humerus; two bones of the fore-arm; a carpus, of which the bones were too small and soft to be reckoned; a metacarpus and phalanges.

Organs of Sense.—The ear is the only one which Cuvier could observe accurately; it seemed to resemble that of the salamander. In the outer side of the bone inclosing the labyrinth, is an oval aperture, simply closed by a cartilaginous plate, covered by soft parts.

Organs of Circulation and Respiration.—There is a single auricle of considerable size, with its circumference denticulated, receiving all the blood of the body, and the lung; two large valves are placed at the mouth of the vena cava. This auricle communicates with the ventricle by a single orifice; and the blood departs from the latter by the aorta only. The heart is therefore exactly the same as that of the frog, the salamander, and of fishes.

The trunk of the aorta, or rather of the vessel, which in fishes is called the branchial artery, is furnished with fleshy and thick sides, and its basis has three strong valves. It divides into three branches on each side for the three branchial tufts, and no branch goes from it to any other part. These arterial branches become attached to the three cartilaginous arches in their way to the branchiæ; but they form no plexus on them, which proves that branchiæ are not attached to these arches as in fishes, and as Garden, Ellis, and Camper imagined in the firen.

Arriving at the branchial tufts, the arteries ramify over all their subdivisions, and the veins bring back the blood in a contrary direction. The same circumstances may be seen in the branchiæ of young aquatic salamanders, in which perhaps the circulation of the blood can be more easily observed with the microscope, than in any other animal organ.

Having quitted the tufts, the branchial veins assume the texture of arteries, and join together, towards the spine, to form the descending aorta; but they produce, before their union, the branches which in other animals arise from the ascending aorta, that is, those of the head, arms, and lungs: the latter come from the third of these branchial veins converted into arteries.

The lungs are two long cylindrical bags, extending to the posterior end of the abdomen, and then bent forwards. The veins and arteries form a loose network on their membrane. Air enters them through a larynx placed on the os hyoides, and opening between two small rounded margins placed vertically. A very slight cartilaginous prominence is observable on each side in its interior, and the glottis is between these: but there is no chorda vocalis with a sharp edge. Yet it does not follow that the observers, who have ascribed a voice to the firen, are inexact; for the approximation of the two prominences just mentioned would be sufficient for its production.

The trachea is a simple membranous, white, and thick canal, without any perceivable cartilaginous rings.

Organs of Digestion.—We have already mentioned the jaws and teeth. The tongue is not fleshy, nor very moveable: it is supported, as in fishes, by the anterior extremity of the os hyoides. It does not resemble that of the salamander, and much less that of the frog, both of which are more free behind than in front, and have a very glandular surface.

The œsophagus is folded longitudinally. The coats of the stomach are moderately thick; it first swells a little, then

REPTILES.

then becomes muscular and contracted, and is narrower than the duodenum. The latter is the widest part of the intestine, which becomes smaller towards the anus. Although longer than the abdominal canal, and consequently forming several slight turns, it exhibits no great folds. There is no cæcum, nor any remarkable change of structure to point out the distinctions of different kinds of intestine. The pylorus has no valve; the mucous membrane of the stomach is smooth; that of the intestine has papillæ like small scales.

The canal is supported by two parallel mesenteries, of which the right adheres to the whole length of the liver. There is no omentum.

The liver is black, elongated, and occupies more than three-fourths of the length of the abdomen. The gall-bladder is lodged in a deep groove towards its middle, and furnishes a single canal, opening into the intestine a little beyond the pylorus. No duct could be perceived coming directly from the liver, but such a one might have been confounded with the numerous mesenteric vessels.

A slender and very long spleen is attached to the mesentery of the left side, and occupies more than three-fourths of the length of the abdomen.

Organs of Generation.—The individual examined by Cuvier was a female. The ovaries were considerably developed, about one-fourth of the length of the abdomen, oblong, composed of lobes, filled with very visible ova, although so flaccid that they probably did not approach to the size which they would have reached in the season of reproduction. A short and straight oviduct was closely connected to the kidney: this part was very different from the long tortuous tubes of the frog and salamander, and approached to the structure of fishes.

Organs of Secretion.—The kidneys were small, well supplied with blood-vessels, and situated at the sides of the rectum. The bladder elongated, and not divided as in frogs.

The conclusions drawn by Cuvier from the preceding account are; 1. That the firen, into whatever state it may pass, is a distinct animal, different in all the details of its organisation from the salamanders and their larvæ which we are acquainted with.

2. That it is very certainly not destined to possess hind feet, and consequently is a biped reptile.

3. There is no reason to suppose that it ever loses its branchiæ, since it is found to possess them at the largest size to which we know of its reaching, and the unanimous testimony of those, who have seen the animal in its native country, proves that no individual has ever been seen without them.

4. That it is essentially different from fishes in its osteological structure, and even in the organisation of the branchiæ.

5. That it therefore constitutes a particular genus of batracian reptiles, preserving always the double respiratory organs; and may be considered as a permanent larva of that family.

Anatomy of the Proteus Anguinus.—This animal was first noticed in the Synopsis Reptilium of Laurenti, in 1768. Scopoli gave a more minute account of it in 1772, in his Annus quintus Hist. Nat. p. 75. Naturalists were divided in opinion, whether it should be regarded as a perfect animal, or only as the larva of some reptile. An excellent description of it, both as to its external characters and structure, was published in the Philosophical Transactions for 1801, pt. 2, by Dr. Schreibers of Vienna, in a paper entitled "An historical and anatomical Description of a doubt-

ful amphibious Animal of Germany, called by Laurenti Proteus Anguinus." Cuvier has since described it in his Recherches sur quelques Reptiles douteux.

The individual examined by Cuvier was 0.25 of a metre in length, and of the size of the little finger: Mr. Schreibers saw one of 0.33, or 13 English inches. The body is slightly compressed, and grooved at the sides, like the firen. The tail is more flattened, and furnished at its edges and end with a fin, which does not reach either above or below farther than the anus. The feet are slender; the knee and elbow being about their middle, and directed as in the salamanders; the fore-feet are terminated by three equal toes without nails, the hind-feet by two only; a combination, which is hitherto unique in the animal kingdom.

The head has some resemblance to that of an eel; the opening of the mouth is of moderate size, and furnished with thin lips. The nostrils are a longitudinal slit on each side, parallel to the side of the upper lip. No eye is perceptible externally; but when the animal is skinned, it is seen under the integuments as a black point, about the thirtieth of a line in breadth.

In the depression produced by the muscles at the sides of the cranium are seen the openings of the branchiæ. They are three, covered in some degree by a prominence of the skin, supported by a muscular stratum. The branchiæ are three small appendages, of a red-blood colour in the living animal.

The skin is whitish, soft, smooth, and presents some small prominences, when examined with a magnifying glass.

Osteology.—When the muscles, that swell the cranium externally, are removed, it appears flat, and quite on a level with the face; the latter terminates in a point in front. The middle of the cranium has its sides parallel; the posterior part swells out in the situation of the prominences to which the lower jaw is articulated, which are directed forwards. Behind, the occiput has two lateral cristæ for the muscles. The head is articulated with the atlas by two condyles: the under surface of the cranium is very flat.

There is no distinct zygomatic arch, orbit, or temporal fossa.

All round the upper jaw is a row of small pointed and vertical teeth; and in front only a small additional row before the others. The inferior jaw has a single row of teeth. Its two branches are nearly rectilinear, and make an angle of about 45°. It has no ascending branch, and the coronoid process is inconsiderable. All these parts are well ossified and firm; and, although the sutures are still visible, we cannot fail to see that the bones belong to an animal very near the adult state.

The bony apparatus of the gills is much more firm than in the firen or axolotl, and somewhat differently composed. The hyoideal branches are slender, and suspended to the sides of the cranium behind the articulation of the lower jaw. The os hyoides is short and thick, and supports behind two pieces equally short and thick, which diverge a little. The first arch of each side, which is the largest, is articulated to the extremity of one of these pieces, and has the two other arches attached to its posterior edge.

There are fifty-six vertebrae: the pelvis is attached to the thirty-first; and the twenty-five following belong to the tail. Six only of these vertebrae, beginning with the second, support rudiments of ribs, still smaller than those of the salamander and the firen.

All the vertebrae, excepting the last of the tail, are perfectly ossified: their form is peculiar to this species.

Organs of Digestion.—The tongue is short, with little power of motion in front, and supported by the anterior

REPTILES.

extremity of the os hyoides. The intestinal canal extends nearly in a straight line through the abdomen. The œsophagus is folded longitudinally; and the stomach is only a rather larger portion of the canal, not marked by any constriction. There is neither cæcum nor large intestine. An oblong liver, pointed at the two ends, of a blackish-grey colour, with two notches in its left edge, occupies about two-thirds of the length of the animal. A large gall-bladder, attached to the internal surface of the liver, pours the bile into the intestine by a short canal. The pancreas is small and narrow, and attached to the intestine opposite to the gall-bladder. An oblong narrow spleen is attached to the mesentery, and is about one-fourth of the length of the liver. The mesentery is simple, and has the usual vessels. There is no omentum.

The Organs of Circulation are the same as in the firen, except that the branchial veins unite together, to form the descending artery, rather lower down.

Organs of Respiration.—The branchiæ are moved, as in the axolotl, the firen, &c.: but no reptile has so small a proportion of lung as the proteus. There is no larynx, properly so called, only a small opening at the bottom of the pharynx, which is the entrance of a common crescent-shaped cavity, the angles of which are prolonged to form the lungs. The latter are merely two very thin membranous canals, terminated by a slight dilatation, presenting in their interior no division into cells, and exhibiting very few blood-vessels on their parietes. When we consider how little difference there is between such lungs and the forked air-bladders of some cartilaginous fishes, we can hardly help concluding that there is some analogy between the two organs.

Organs of Generation.—In the female dissected by Cuvier, oblong lobed ovaries, full of very distinct small ova, were situated towards the lower part of the abdomen, at the sides of the rectum. Very long oviducts, making several turns, like those of the salamander, ascend to the anterior third part of the cavity.

Organs of Secretion.—There are kidneys and a bladder, as in the salamanders: the former are very long, and pass high up in the abdomen.

All these observations, and particularly those concerning the osteology, make it clear that the proteus is a particular animal, different from all hitherto known: they also make it very probable that it is an adult animal, not destined to undergo any further change of state.

A proteus taken alive threw up from its stomach many shells of the genus *helix*, but it would not take these shells or any other food, and became daily more languid and weak. It seemed, when alive, very torpid, and moved but seldom; it swam, however, sometimes, with the help of its broad tail, very swiftly, in every direction. The first days it crept slowly on the bottom, and seemed to look for food; it often took a shell into its mouth, but gave it out again, swallowing none. Several times it rose to the surface, stretched its head out of the water, and took in air, but returned directly to the bottom. It uses its feet in creeping on the bottom, and in ascending along the sides of the vessel, if of wood. It creeps very slowly or deliberately, inasmuch that this motion seemed quite characteristic of the animal.

It often produces a hissing kind of noise, pretty loud, more so than one should expect from the size of the animal, and resembling that produced by drawing the piston of a syringe.

All the habits of the proteus designate a slowness and weakness agreeing very well with the excessive smallness of

its pulmonary organs, and the very inconsiderable extent of their surface.

It is a very rare animal, having been hitherto found, and that in very small numbers, only in those lakes of Carniola, which are celebrated on account of their subterranean communications and the singular phenomena which result from them. That of Cirknitz is the most famous, and is regarded as the source of all the others. According to Laurenti, the first proteus was found in this: but Schreibers assures us that it only inhabits the lake called Sitticher See, communicating with the Cirknitz; and that it is thrown out in the overflowings, which occur once or twice a-year.

Cuvier thinks it probable that its natural abode is in the subterranean communications extending from one lake to the other. It has, in fact, all the characters of a subterranean, as well as of an aquatic, animal. Its small eyes, concealed and rendered useless by an opaque skin, recall to us the blind rat (*zemni*, *mus*, or *spalax typhlus*) which lives under ground, and has exactly the same organization.

In a letter to Cuvier, Schreibers informed him that, since the publication of his paper in 1801, he has met with several individuals, all perfectly alike, among which he had in vain sought for one without the branchiæ. That he himself has some, which have been two years in his possession, alive and well, although they have taken no food the whole time.

For the external figure and anatomy of this animal, see the plates subjoined to Dr. Schreibers' paper in the *Phil. Trans.* and pl. 13 of the *Recueil d'Obs. de Zool. et d'Anat. Comparée de Humboldt*, v. 1.

Another of these doubtful animals has been figured in the *Annales du Muséum*, v. 10. p. 230. pl. 17. under the name of *protée*, or *salamandre tetradaçtyle*, by Lacépède, who has there described its external conformation. It possesses branchial appendages, eyes covered by the epidermis, and two rows of fine teeth. As only the specimen described in the above quoted work is known (without any information about the quarter whence it came), its anatomical structure has not been examined. All the appearances lead us to expect an internal organization like those of the proteus and firen.

The following are the principal sources of information on the subjects of the preceding article. Cuvier, *Leçons d'Anatomie Comparée*. Blumenbach's *Manual of Comparative Anatomy*; also his *Specimen Physiologiæ comparatæ inter Animalia calidi et frigidi sanguinis*, 4to. Goett. 1787; or in *Commentation. Soc. Reg. Scient. Goettingenf.* v. 8. Daudin, *Histoire Naturelle des Reptiles*, in the 8vo. edition of Buffon by Sonnini, 8 tomes. Brongniart, *Memoire sur une nouvelle Classification des Reptiles*. Lacépède, *Histoire Naturelle des Quadrupèdes ovipares et des Serpens*. Latreille, *Hist. Nat. des Salamandres de France*, avec figures. Schneider, *Historia Amphibiorum*. Schoepff, *Historia Testudinum*, 4to. Schneider, *Naturgeschichte der Schildkröten*. Roefel, *Historia Ranarum*. *Memoires pour servir à l'Histoire des Animaux*. Tyfon's *Anatomy of a Rattle-snake*, *Phil. Trans.* v. 13. Swammerdam *Biblia Naturæ*. Charas, *Nouvelles Expériences sur la Vipère*. Caldesi, *Osservazioni Anatomiche intorno alle Tartarughe*, 4to. Hermann, *Tabulæ affinitatum Animalium*. Spallanzani's *Dissertations*. Cuvier, *Recherches sur les Reptiles douteux*, in Humboldt, *Recueils d'Observ. de Zool. et d'Anat. Comp.* v. 1. Various papers by Cuvier and Geoffroy St. Hilaire, in the *Annales du Muséum*.

REPTILES are likewise used, abusively, for plants which creep on the earth, or on other plants, as wanting strength of stalk to sustain themselves.

Such

Such are cucumbers, melons, &c. ; such also are ivy, the vine, and bryony.

REPTON, in *Geography*, a considerable town in the hundred of Repton-and-Gresley, and county of Derby, England, is situated near the banks of the river Trent, at the distance of eight miles S.W. from the town of Derby, and four N.E. from Burton-upon-Trent in Staffordshire. Among antiquaries it is celebrated as the scene of the capital of the Mercian monarchy, and the burial-place of several of its sovereigns. At that period it was called Hreopandune; and is conjectured by some to have risen upon the ruins of the Roman station Repandum; and the town is called Reppendune in ancient deeds. In the Saxon annals Repton is said to have been noted for a noble monastery of men and women, established, under the government of an abbess, previous to the year 660. This abbey was destroyed by the Danes in the reign of Buthred, the last king of Mercia, and remained in a desecrated state till the year 1172, when it was refounded as a priory by Matilda, widow of Ranulph, second earl of Chester, who bestowed upon the monks the tithes of Repton, and considerable estates in the neighbourhood, besides Bartlow in Essex, and lands at Grandden, in Huntingdonshire. At the dissolution its revenues were estimated at 167*l.* 18*s.* 2*d.* In the original structure were deposited the remains of several of the Mercian kings; as were likewise those of Rynechardus, brother to Sigebert, king of the West Saxons. Some portions of the later buildings are yet in existence, being converted into a school-house and apartments for the master and usher. The school-room, as appears from the windows and other traces, was either the refectory, or the hall, of the priory. It is supported by a row of strong round columns, with pointed arches. At the northern extremity of this room was the dormitory; and on the east side were situated the cloisters, the area of which is now a garden. Adjoining the cloisters stood the church which Fuller, in his "Church History," describes as an elegant and spacious structure, supported in the interior by pillars of alabaster, fragments of which have been occasionally laid open. Foundations of other buildings, besides those mentioned, may still be plainly traced in various directions; and on the site of the prior's lodging is a mansion called Old Trent, built about a century ago, which displays, towards the water, a curious brick tower with an ornamental cornice, part of a former building, erected by Prior Overton in the reign of Henry VI.

Repton consists chiefly of one street of scattered houses, extending about a mile in length, and watered by a fine stream, which discharges itself into the Trent. At the

lower end of the town stands the parish church, a large, handsome edifice, ornamented with a fine spire two hundred feet high. Tradition affirms that the present is the third church which has occupied the same site; and there can be no doubt that parts of it are of different and distant dates. The nave and side aisles seem to be of the reign of Edward III.; but the chancel is probably more ancient, as its columns are massive, and its arches semicircular. Beneath this part of the church is a crypt, bearing a strong resemblance, in form and ornaments, to the crypt under Canterbury cathedral, and also to that under St. Peter's in the East, at Oxford. In the interior of this building are several handsome monuments to the memory of the Thacker family. Within a clove behind the church, a labourer some years ago discovered a cemetery, which contained among many other human skeletons, one of an extraordinary size, measuring nine feet in length. This discovery is noticed by Dr. Pegge in the *Philosophical Transactions* for the year 1734. An old stone cross, consisting of a single shaft, placed upon eight octagonal steps, stands in the area fronting the church. The parish of Repton, according to the parliamentary returns of 1811, contains 326 houses, and 1648 inhabitants, who are chiefly engaged in pursuits connected with agriculture.

At a short distance from Repton is Sudbury, the seat and property of the family of Vernon, which is of great antiquity, deriving its descent from Richard de Vernon, a Norman lord, who accompanied the Conqueror to England; and was one of the seven barons created by Hugh Lupus, the great earl of Chester. Sir Ralph de Vernon, who was alive in the reign of Edward II., is said to have reached the extraordinary age of 150 years. Sudbury church, an ancient fabric, standing in the garden near the house, is decorated with many sepulchral tombs to members of this family. One, in commemoration of Catharine, daughter to the late lord Vernon, is remarkable for the beauty of the epitaph, which was written by William Whitehead, poet-laureat.

At Egginton, on the banks of the river Dove, west of Repton, is a seat of sir Henry Every, whose family was originally seated in Somersetshire. Part of the old mansion here was destroyed by fire in the year 1736, and the present house then erected on its site.

Bretly park, the seat of the earl of Chesterfield, is about three miles S.W. of Repton. About three miles E. of Bretly is Calke hall, the seat of sir Henry Harpur, bart. The house is a spacious quadrangular edifice, seated in a park surrounded by eminences. *Beauties of England and Wales*, vol. iii. by John Britton and E. W. Brayley, 1802.
